Spontaneous Neoplastic Lesions and Test Article Induced Neoplastic Lesions in P53 Mice and rasH2 Mice

Peter Mann, DVM, Ph.D.

EPL, USA

Several strains of genetically engineered mice are currently being used as alternatives to long term carcinogenesis studies for submission to regulatory agencies. The most commonly used mice include the p53 heterozygous knockout mouse, the Tg.AC transgenic mouse and the rasH2 transgenic mouse. Each of these models has specific genetic modifications which make them attractive for the study of carcinogenicity of novel xenobiotics.

The background and utility of each model will be discussed. Common spontaneous and induced lesions will be covered in detail. Finally, the acceptance of these models by regulatory agencies in several countries will be addressed.

Genetically Engineered Mice in Toxicology

Peter C Mann, D.V.M.

Major Players in Genetically Engineered Mice, Toxicology Division

- Tg AC
- p53 +/-
- rasH2

EPL

Principal Hypothesis

- Transgenic mice with specific genetic alterations critical to tumorigenesis but which are insufficient to induce neoplasms in a specified time are candidates for rapid cancer bioassays
- Exposure to transpecies carcinogens will result in rapid induction of tumors

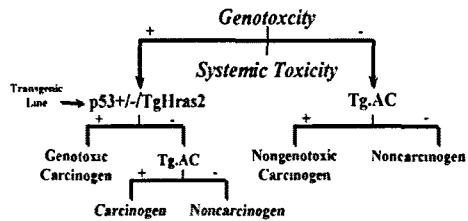

EPL

Protocols

- Typical protocol calls for a 6-month exposure
- All protocols are based primarily on reduced latency to tumor development
- Spontaneous/background tumors very rare prior to 12 months

EPL

Use of Transgenic Models in Drug and Chemical Safety Evaluation

EPL
Decision tree for use of transgenic mouse lines to complement conventional rodent bioassays (Adapted from Tennant et al., 1995)

EPL

Tg.AC Transgenic Mouse

- Mutated Harvey-ras oncogene
- Multiple copies on chromosome 11
- Expression of transgene is inducible
- Expresses in skin - genetically initiated
- Induction of papillomas - reporter phenotype
- Detects both mutagenic and non-mutagenic agents

EPL

*Tumors in Tg.AC Transgenic Mice
Spontaneous Tumors*

- | | |
|---------------------------------|-------------------------------|
| • Odontogenic Tumor | • Erythroleukemia |
| • Forestomach Papilloma | • Ovary Teratoma |

EPL

rash2 Transgenic Mouse

- Has normal coding region of human c-Ha-ras gene, Mutation in last intron
- Over-expression of gene in tumors and normal tissues
- CB6F1
- Few lesions at 6 months of age

EPL

rash2 Transgenic Mouse - Advantages

- Carries a human oncogene
- More rapid onset of tumors
- Higher incidence of tumors
- Target tissues correspond to bioassays

EPL

EPL

Transgenic Mice at the Regulatory Agencies

EPL

FDA

- Congressional Mandate
 - Faster Review
 - Less Regulatory Burden
- ICH Guidance
 - Approved *in vivo* alternative to 2nd rodent study

EPL

FDA

- Transgenic Model may be chosen as:
 - Alternative to a 2nd 2 year rodent study
 - Complimentary or confirmatory for equivocal findings
 - To set priorities
 - As an option to repeating a 2 year study
 - Inadequate 2 year study
 - Change in clinical indication or human exposure
 - To support differing completion of a 2 year study
 - To assess carcinogenic potential of contaminants

EPL

EPA

- Different Levels of information needed
- Many pollutants to consider
- Emphasis on mechanistic data in new laws
- Alternatives considered
 - Transgenics
 - Medaka
 - Neonatal Mouse Model

EPL

EPA

- Does EPA accept the use of alternatives now?
 - Yes - As part of weight of evidence
 - Yes - To help understand mode of action
 - No - In lieu of tumor findings in a 2 year Bioassay for FIFRA or TOSCA

EPL

Japan

- Pharmaceuticals - either 2 rodent carcinogenicity studies or 1 rodent and 1 short term alternative test
 - Alternatives
 - Transgenic Model
 - Initiation-Promotion
 - Neonatal Mouse
- Pesticides - 2 rodent carcinogenicity tests

EPL

Issues

- What type of carcinogens do we wish to identify? or What type of carcinogens is it OK not to identify
- What is the gold standard?
- How will the results be used?
- What is the likely outcome of contemporary validation trials using genetically altered mice?
- What opportunities are afforded by the efforts?

EPL

What type of carcinogens do we wish to identify? or What type of carcinogens is it OK not to identify?

- Trans-species, multi-site genotoxic carcinogens
- Six-month carcinogens
- High-dose carcinogens
- Tissue-specific carcinogens
- Carcinogens that are mechanistically relevant to humans

EPL

What is the gold standard?

- Conventional two-year rodent bioassay
- Human carcinogens
- Organotrophism

EPL

How Will Results Be Used?

- As substitute for conventional 2-year bioassay
- As adjunct in weight of evidence
- To define dose response
- To screen chemicals prior to conventional testing
- To help define mechanisms

EPL

What is the likely outcome of contemporary validation trials using genetically altered mice?

- Déjà vu

EPL

*What opportunities are afforded
by the efforts?*

- A chance for progress in improving how potential human carcinogens are identified
- Stage set for not being limited to 4 cell conventional testing
- Strengthen the scientific base for risk assessment

EPL
