Postoperative Esophageal Leak (Fistula)

JAE ILL ZO
National Cancer Center

Introduction

- Esophageal leak is one of the most serious complications with significant morbidity and mortality in esophageal surgery
- Historically leak rate was 3–12% (thoracic), 10–25% (cervical), and mortality rate was 50–71%(thoracic), less than 20%(cervical), however , recently lower mortality (3.3–8.5%) with improved treatment.
- Multiple predisposing factors were evaluated.
- Many leak can be managed conservatively, significant patients still require re-exploration.

Definition of Anastomotic leakage

Surgical Infection Study Group.1991

Leak grade	Definition	Outcome
Radiological (I)	No clinical sign	Usually nonfatal
Clinical minor(II)	Local inflammation cervical wound X-ray contained leak(thoracic anastomosis) Fever, ↑ WBC, ↑CRP	Low mortality
Clinical major(III)	Severe disruption on endoscopy Sepsis	High mortality
Conduit necrosis (IV)	Endoscopic confirmation	Usually fatal

Typical pattern of presentation

JD Urschel Am J Surg 1995

Category of leak	Time	Etiology	Presentation
Early fulminant	<48hr	Gastric necrosis Technical error	Septic shock Foul C-tube drainage
Clinical apparent thoracic	2–7 days	Multiple factors	Septic deterioration C-tube drain GI contents Pleural effusion
Clinical apparent cervical	2–10 days	Multiple factors	Fever Inflamm neck wound Drainage via neck drain
Clinical silent	7 days	Multiple factors	Asx. Small contained Leak on esophagography

Predisposing factors

Inherent risk factors

- Absence of serosal layer
- Longitudinal orientation of muscle fibers
- Extra-peritoneal position of anastomosis
- Cyclical negative intrathoracic pressures
- Technically difficult anastomosis in thorax

Predisposing factors

Preoperative factors (Patient related factors)

- DM
- Malnutrition
- Serum albumin < 3g, Weight loss
- Cardiovascular disease
- Respiratory insufficiency
- Preoperative chemotherapy +/- Radiation
- Salvage esophagectomy

Predisposing factors

Operative factors

- Positive resection margin
- Technical difficulty
- Arterial insufficiency of conduit
- Venous stasis
- Splenectomy

Predisposing factors

Postoperative factors

- Gastric distension
- Re-exploration due to bleeding
- Peri-operative hypotension/ use of vasoconstrictors
- Respiratory failure; Epidural analgesia, Smoking
- Pronged ventilator support
- Sustained hypoxia; ARDS

Technical point

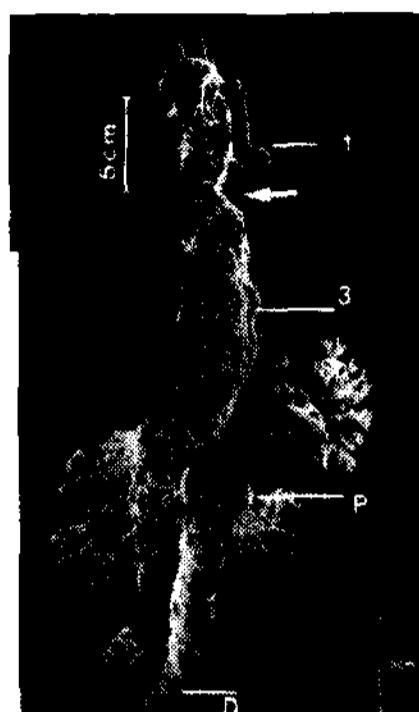

- Atraumatic mobilization of gastric fundus
- Avoid traction sutures or suction device
- Water tight anastomosis without excessive sutures
- Adequate mobilization of conduit
- Correct orientation of conduit
- Compression free passage of conduit in thoracic inlet
- Familiarity of vascular anatomy of different conduit

Blood supply of Stomach (1)

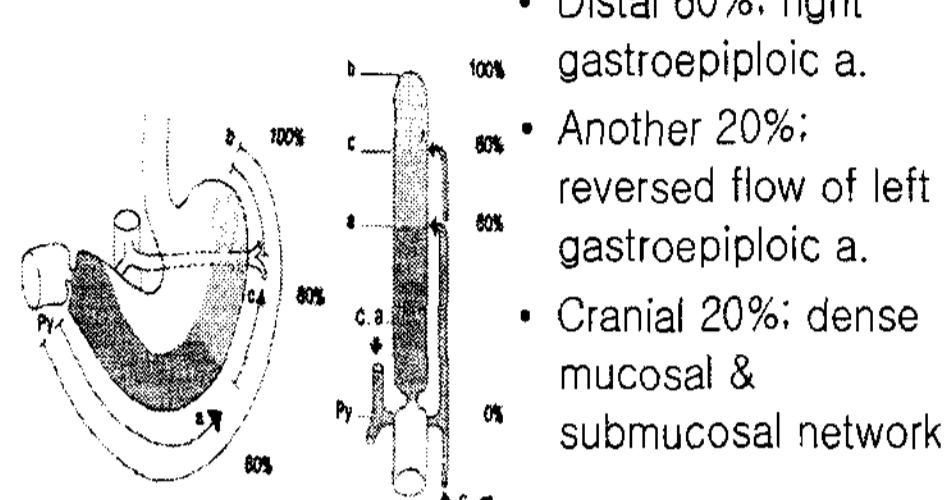

- celiac axis & sup. mesenteric a.
- Rt. gastroepiploic a., anastomosis with Lt. gastroepiploic a
- mucosal & submucosal network
- Rt. gastric a does not contribute gastric tube

Venous Drainage of Stomach (2)

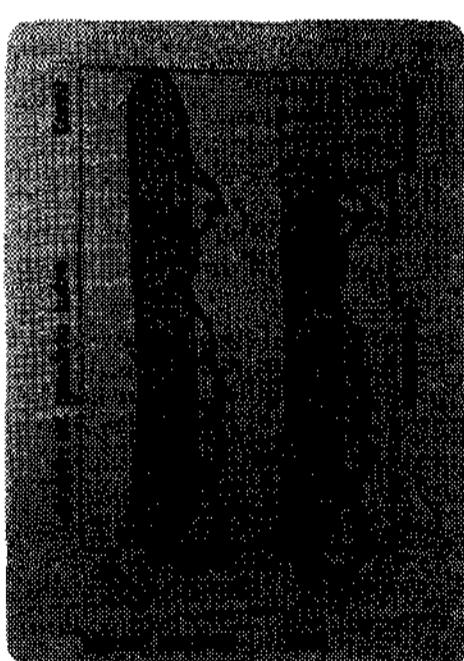

- Follows the pattern of arterial vascular supply

Blood supply of Stomach (3)

- Distal 60%; right gastroepiploic a.
- Another 20%; reversed flow of left gastroepiploic a.
- Cranial 20%; dense mucosal & submucosal network

Blood supply of Stomach (4)

- Safe blood supply: 4–5cm margin from greater curvature side
- Avoid squeezing, bruising, kinking, tension to prevent interruption of submucosal network, ischemia, leakage, dehiscence, stricture

Detection

- Insufflating conduit with air after saline filling chest
- Scanning laser Doppler flowmetry (NH Boyle, J Am Coll Surg, 1999)
- Gastric fundus oximetry measurement (JA Salo, Am J Surg, 1995)

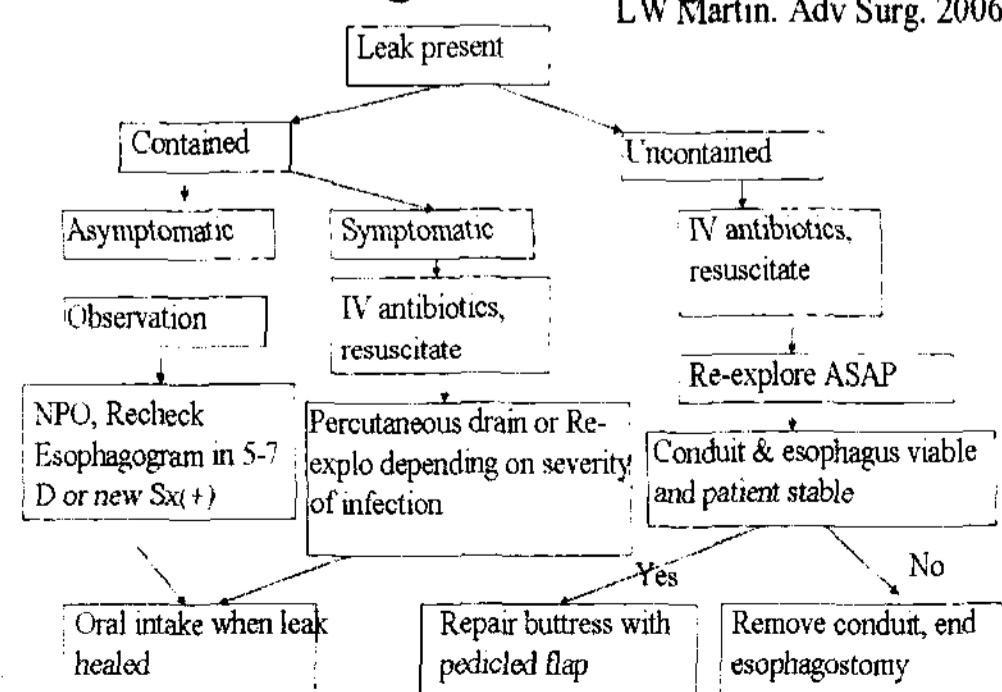

Detection

Postoperative

- Clinical symptom and sign
Fever, Sign of sepsis, abnormal drainage, Wound infection, GI hemorrhage, New pleural effusion, Pneumothorax, TE fistula symptom
- Esophagography
- Intramucosal gastric pH monitoring
- Endoscopy; experienced endoscopist with pediatric endoscope
- CT of the chest

Leak Management algorithm

LW Martin. Adv Surg. 2006

Management

General leak Mx. without symptom

- NPO
- Observation for sign of deterioration
- Nutritional support
- Antibiotics

Invasive Mx. with symptom

- Adequate IV volume, Antibiotics
- Chest CT ,Image-guided drainage
- Chest tube drainage
- Endoscopy; conduit ischemia
- Re-operation

Management

Uncontained leakage Mx

- Adequate IV volume, Antibiotics
- Reoperation- BFS, GFS
 1. Debridement and decortication
 2. Primary repair
 3. Tissue flap reinforcement
 4. Take down and cervical esophagostomy
- Supportive care

Management

When to divert

- Too unstable to repair or reconstruct
- Questionable conduit viability or necrotic
- Local complication of leak; TEF, Esophago-vascular fistula
- Failure of primary repair

Management

Tracheo-esophageal fistula Mx.

; acute, non-controlled fistula

- Primary repair
- Repair with muscle flap interposition
- Airway stenting
- Esophageal diversion with airway repair
- Repair with pedicled pericardium

Management

Alternative Mx.

- Stent insertion
- 1. Polyflex esophageal stent(RK Freeman JTCS 2007)
- 2. Self-expandable covered metal tracheal type stent (J Lindermann Ann TS 2008)
- 3. Covered Mushroom-shaped metallic stent(xw Han,Ann TS 2006)
- 4. Silicone covered self-expanding metal stent(WKH Kauer, Surg Endosc. 2008)
