## $[\forall KVN-01]$ Candidates for the young stellar outflows: Water and Methanol masers from young stellar objects

Wanggi Lim<sup>1</sup>, A-Ran Lyo<sup>1</sup>, Kee-Tae Kim<sup>1</sup> and Do-Young Byun<sup>1</sup> <sup>1</sup>Korea Astronomy and Space Science Institute

We conducted simultaneous 22GHz water maser and 44GHz class I methanol maser surveys of newly-identified 282 H2 emission features from the 2.122µm H2 narrowband image survey in the Galactic plane (UWISH2 project) using Korea VLBI Network (KVN) 21-m radio telescopes. We detected 16 and 13 new water and methanol maser sources, respectively. This result indicates that at least ~5% of the H2 emission features originate from young stellar objects (YSOs) that are in the right physical condition to produce the water and methanol masers. The masers are closely related to the current outflow activities in the Galactic plane. The power sources of these 23 diffused/collimated H2 emission features (six sources are detected for both masers) are likely to be intermediate-to high-mass YSOs, based on a comparison with the maser luminosities of other well-studied YSOs. Both maser velocities are mostly close to their own systemic velocities within 5 km/s, even though water masers generally show larger variabilities in the line intensities, velocities, and shapes than methanol masers. We also discovered three new water maser sources with high-velocity components: ~25 km/s red-shifted CMHO019, ~50 km/s blue-shifted CMHO132, and ~120 km/s blue-shifted CMHO182. In particular, we propose that the dominant blue-shifted water maser of CHMO182 could become a unique laboratory for the study of high-mass stellar jet and their accelerations.

## [7KVN-02] Time Monitoring Observations of SiO and H<sub>2</sub>O Masers Using the KVN

We present the interim results of simultaneous time monitoring observations of SiO v=1, 2, J=1-0,  $^{29}$ SiO v=0, J=1-0, and H<sub>2</sub>O  $_{616}-5_{23}$  maser lines toward about 60 relatively strong SiO and/or H<sub>2</sub>O maser sources using the single dishes of the Korean VLBI Network from 2009 September to 2012 June. These monitoring sources are composed of representative semiregular variables, Miras, water fountain sources, preplantary nebulae and SiO maser sources of star forming regions etc. The variations of intensity ratios between SiO and H<sub>2</sub>O masers and velocity structures are investigated according to stellar optical phases and observational epochs. Several individual sources which show an interesting feature will be presented here.
