Vanadium dioxide (VO₂) is a strongly correlated oxide exhibiting a first-order metal-insulator transition (MIT) that is accompanied by a structural phase transition from a low temperature monoclinic phase to a high-temperature rutile phase. VO₂ has attracted significant attention because of a variety of possible applications based on its ultrafast MIT. Interestingly, the transition nature of VO₂ is significantly affected by stress due to doping and/or interaction with a substrate and/or surface tension as well as defects. Accordingly, there have been considerable efforts to understand the influences of such factors on the phase transition and the fundamental mechanisms behind the MIT behavior. Here, we present the influences of oxygen deficiency, hydrogen doping, and substrate-induced stress on MIT phenomena in single-crystalline VO₂ nanobeams. Specifically, the work function and the electrical resistance of the VO₂ nanobeams change with the compositional variation due to the oxygen-deficiency-related defects. In addition, the VO₂ nanobeams during exposure to hydrogen gas exhibit the reduction of transition temperature and the complex phase inhomogeneities arising from both substrate-induced stress and the formation of the hydrogen doping-induced metallic rutile phase.

Ag-modified BiOX (X=Cl, Br and I) Plates for Photocatalytic Dye Removal

이승원, 최영인, 이주현, 박요한, 손영구*

Department of Chemistry, Yeungnam University

Ag-modified BiOX (X=Cl, Br and I) nanoplates were synthesized by an ion-exchange reaction. We examined the fundamental properties by scanning electron microscopy (SEM), electron transmission microscopy (TEM), X-ray diffraction, UV-visible absorption, Fourier-transform infrared and photoluminescence spectroscopy. The adsorption and photocatalytic performances of the catalysts were tested with dyes under UV and visible light. A chemical scavenger method was employed to test the roles of active species ($\cdot\text{OH}$, $\cdot\text{O}_2^-$ and h^+) and understand photodegradation mechanism. Photoluminescence spectroscopy was used to examine $\cdot\text{OH}$ radical formation using terephthalic acid during photoirradiation.
