The Kinetics and Mechanism of the Hydrolysis of a 1, 1-Dicyano-2-p-dimethylaminophenyl-2-chloroethylene

Tae-Rin Kim and Tae-Seong Huh*

Department of Chemistry, College of Science and Engineering, Korea University, Seoul, Korea

(Received Sept. 7, 1974)

요 약. 여러 pH에서 1, 1-dicyano-2-p-dimethylaminopheny1-2-chloroethylene(DPC)의 가수분 해 속도상수를 측정하고 넓은 pH 범위에서 잘 맞는 반응 속도로식을 구하였다. 이 식에 의하면 넓은 pH 범위에서 DPC에 대한 가수분해 반응메카니즘을 잘 설명할 수 있다. pH3이하와 7.5이상에서는 속도상수는 hydronium ion 과 hydroxide ion 농도에 각각 비례한다.

또 pH 3~7.5 사이에서는 물, hydronium ion 과 hydroxide ion 이 DPC 의 가수 분해에 촉매 역활을 함을 알았다.

Abstract. The rate constants of hydrolysis of 1, 1-dicyano-2-p-dimethylaminophenyl-2-chloroethylene(DPC) were determined at various pH and the rate equation which can be applied over wide pH range is obtained. From the rate equation the mechanism of the hydrolysis of a DPC over wide pH range is fully explained; below pH 3 and above pH 7.5, the rate constant is proportional to the concentration of hydronium ion and hydroxide ion, respectively. However, in the range of pH 3 to 7.5, water, hydronium ion and hydroxide ion catalyze the hydrolysis of DPC.

1. Introduction

The addition reaction of the double bond having electron attracting group, unlike ordinary carbon double bonds, are electrophilic. During the past decade a great deal of imformation has appeared in the literature^{1~2} concerning the mechanism of nucleophilic addition and qualitative observation to explain a plausible mechanism^{3×5} in basic solution, however, it has been the subject only a few kinetic studies.

Kharash⁶ and Hurd⁷ have suggested a mechanism of the addition of mercaptan to carbonyl compounds in basic media. Stewart⁸ pointed out the alkaline scission of 4-hydroxy-3-methexy- β -nitrostyrene. Walker and Young⁹ also determined the velocity constants and activation energies for the hydrolytic decomposition of chalcone and six ring substituted mononitro derivatives.

^{*}Department of Chemistry, Song Sim Women College, Choon Chun, Korea

Patai and others^{10~12} have studied the elimination of malononitrile from 4, 4-dicyano-3nitrochalcone and malononitrile in methanol. The kinetics of the reaction of barbituric acid with β -nitrostyrene derivatives in non-alkaline media has been reported. ¹³ In acidic media, the cleavage of β -nitrostyrene was suggested by Crowell^{14~15} to take place in a slightly different mechanism. Truce and others¹⁶ have studied the stereochemistry of the mercaptan addition reaction.

The mechanisms of the reaction of mercaptan with maleic anhydride, ¹⁷ methylacrylate, ¹⁸ β nitrostyrene, ¹⁹ ethylcinnamate, ²⁰ has been reported. But for the DPC, the only vinyllic substitution by aromatic amines in acetonitrile was reported. ²¹ The purpose of this investigation is to determine each rate constant of hydrolysis over a wide pH range and to reveal the reaction mechanism.

2. Experimental

The DPC(IV) was prepared according to Josey *et al.*, ²² from ethylformate and potassium malononitrile *via* 1-chlor-2, 2-dicyanoethylene (I), 1, 1, 2-trichloro-2, 2-dicyanoethylene (II) and 1, 1-dichloro-2, 2-dicyanoethylene (III). Recrystallization of the crude material from methanol yielded orange product, mp. 132 °C (lit²²., 132~234 °C).

$$\begin{array}{c} HCOOC_{2}H_{5} + KCH(CN)_{2} \longrightarrow ClCH \cong C(CN)_{2} \\ (I) \\ \rightarrow Cl_{2}CHC(Cl)(CN)_{2} \longrightarrow Cl_{2}C = C(CN)_{2} \\ (II) \\ (III) \\ (III) \\ \rightarrow \frac{CH_{3}}{CH_{3}} > N \longrightarrow \underbrace{\bigcirc}_{Cl} \longrightarrow C \longrightarrow C \\ Cl \\ (IV) \end{array}$$

All buffer solution were prepared from reagent

Vol. 18, No. 6, 1974

grade chemicals(E. Merk) and distilled water. The pH of buffer solutions were confirmed by Zerometric II pH meter(Beckman). The ionic strength was kept constant at 0.1 by adding sodium chloride solution.

The rate vessels used were 100 ml volumetric flasks in the thermostat($25 \,^{\circ}$ C). At zero time, $1 \,\text{m}l$ of a freshly prepared 0.002 M methanol solution of DPC was pipetted into the $100 \,\text{m}l$ flask containing $99 \,\text{m}l$ of buffer solution. The optical density of DPC was determined on a Beckman Model DU spectrophotometer at $445 \,\text{nm}$.

3. Result

The logarithmic plots of optical density of DPC vs. times at 445 nm were linear and used to calculate the first-order rate constants (Fig. 1). The rate constants calculated from the slope for all runs are given in Table 1. Fig. 2. shows the logarithmic plots of k_t against pH. The rate constants for the hydrolysis of DPC at various acetate ion concentration at pH 4.65 are grven in Table 2 and Fig. 3 and known to be a general base catalysis.

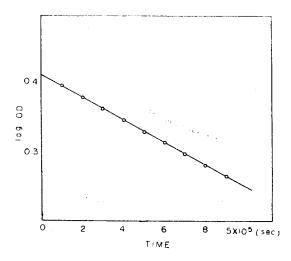

Fig. 1. The plots of log OD of DPC vs. time at pl_{4} 4.50 and 25°C.

Table 1. The rate constants for the hydrolysis of DPC at various pH & 25 °C.

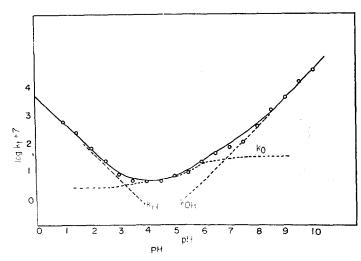

Fig. 2. pH-Kate profile for the hydrolysis DPC at 25 °C.

4. Discussion

constant k_t is given by an expression of the form

$$k_{\rm f} = k_0 + k_{\rm H}a_{\rm H} + k_{\rm OH}a_{\rm OH}$$
$$= k_0 + k_{\rm H}a_{\rm H} + k_{\rm OH} - \frac{K_{\rm IV}}{a_{\rm H}} (1)$$

Where k_0 is the rate constant for the hydrolysis which is insensitive to pH i.e., spontaneous hydrolysis or more accurately, water catalized hydrolysis. While k_{OH} and k_{H} are the rate constants for hydroxide ion and hydronium ion catalysed hydrolysis respectively.

Below pH 3, the iminonium ion is a likely intermediate since it has been shown to form from the nitrile and hydronium ion. $^{23\sim24}$

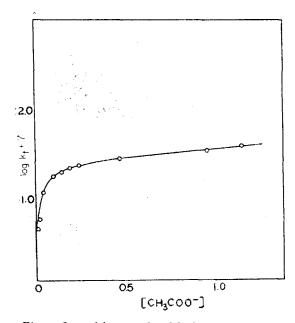

Fig. 3. General base catalyzed hydrolysis of DPC at pH 4.65 and 25 °C.

For explaining these rate terms, following addition-eliminaton mechanism is proposed.

In this mechanism, the first step of the hyd-

$$\begin{array}{c} \operatorname{Arc}_{C}=C & \subset \equiv N & + & \operatorname{H_3O} = \\ \underset{C}{\operatorname{Arc}} = C & \subset \equiv N \\ \operatorname{Arc}=C & \subset \equiv N & \operatorname{Arc}=C & \overset{\circ}{\underset{C}{\operatorname{C}} = NH} & \xrightarrow{\operatorname{Arc}} \operatorname{Arc}=C & \overset{\circ}{\underset{C}{\operatorname{C}} = NH} \\ \end{array} \begin{array}{c} \operatorname{Arc}_{C}=C & \overset{\circ}{\underset{C}{\operatorname{C}} = N} \\ \operatorname{Arc} = C & \overset{\circ}{\underset{C}{\operatorname{C}} = N} \\ \xrightarrow{\operatorname{Arc}} & \overset{\circ}{\underset{C}{\operatorname{C}} = N} \end{array} \begin{array}{c} \operatorname{Arc}_{C}=C & \overset{\circ}{\underset{C}{\operatorname{C}} = NH} \\ \xrightarrow{\operatorname{Arc}} & \overset{\circ}{\underset{C}{\operatorname{C}} = N} \end{array} \begin{array}{c} \operatorname{Arc}_{C}=C & \overset{\circ}{\underset{C}{\operatorname{C}} = NH} \\ \xrightarrow{\operatorname{Arc}} & \overset{\circ}{\underset{C}{\operatorname{C}} = N} \end{array} \begin{array}{c} \operatorname{Arc}_{C}=C & \overset{\circ}{\underset{C}{\operatorname{C}} = NH} \\ \xrightarrow{\operatorname{Arc}} & \overset{\circ}{\underset{C}{\operatorname{C}} = N} \end{array} \begin{array}{c} \operatorname{Arc}_{C}=C & \overset{\circ}{\underset{C}{\operatorname{C}} = NH} \\ \xrightarrow{\operatorname{Arc}} & \overset{\circ}{\underset{C}{\operatorname{C}} = N \end{array} \end{array} \begin{array}{c} \operatorname{Arc}_{C}=C & \overset{\circ}{\underset{C}{\operatorname{C}} = NH} \\ \xrightarrow{\operatorname{Arc}} & \overset{\circ}{\underset{C}{\operatorname{C}} = N \end{array} \end{array} \begin{array}{c} \operatorname{Arc}_{C}=C & \overset{\circ}{\underset{C}{\operatorname{C}} = NH} \\ \xrightarrow{\operatorname{Arc}} & \overset{\circ}{\underset{C}{\operatorname{C}} = N \end{array} \end{array} \begin{array}{c} \operatorname{Arc}_{C}=C & \overset{\circ}{\underset{C}{\operatorname{C}} = NH} \\ \xrightarrow{\operatorname{Arc}} & \overset{\circ}{\underset{C}{\operatorname{C}} = N \end{array} \end{array} \end{array} \begin{array}{c} \operatorname{Arc}_{C}=C & \overset{\circ}{\underset{C}{\operatorname{C}} = NH} \\ \xrightarrow{\operatorname{Arc}} & \overset{\circ}{\underset{C}{\operatorname{C}} = N \end{array} \end{array} \begin{array}{c} \operatorname{Arc}_{C}=C & \overset{\circ}{\underset{C}{\operatorname{C}} = NH} \end{array} \end{array} \begin{array}{c} \operatorname{Arc}_{C}=C & \overset{\circ}{\underset{C}{\operatorname{C}} = NH} \\ \xrightarrow{\operatorname{Arc}} & \overset{\circ}{\underset{C}{\operatorname{C}} = N \end{array} \end{array} \end{array}$$

Vol. 18, No. 6, 1974

 $\begin{array}{c} \stackrel{\Phi}{\rightarrow} \stackrel{H_{2}}{\underset{C}{\Rightarrow}} \stackrel{C=NH}{\underset{C}{\Rightarrow}} = \left[\begin{array}{c} \stackrel{\Theta}{\underset{C}{\Rightarrow}} \stackrel{C=NH}{\underset{C}{\Rightarrow}} \stackrel{\Theta}{\underset{C}{\Rightarrow}} \stackrel{C=NH}{\underset{C}{\Rightarrow}} \stackrel{\Theta}{\underset{C}{\Rightarrow}} \stackrel{C=NH}{\underset{C}{\Rightarrow}} \stackrel{\Theta}{\underset{C}{\Rightarrow}} \stackrel{C=NH}{\underset{C}{\Rightarrow}} \stackrel{OH}{\underset{C}{\Rightarrow}} \stackrel{C=N}{\underset{C}{\Rightarrow}} \stackrel{OH}{\underset{C}{\Rightarrow}} \stackrel{C=N}{\underset{C}{\Rightarrow}} \stackrel{OH}{\underset{C}{\Rightarrow}} \stackrel{C=N}{\underset{C}{\Rightarrow}} \stackrel{OH}{\underset{C}{\Rightarrow}} \stackrel{C=N}{\underset{C}{\Rightarrow}} \stackrel{OH}{\underset{C}{\Rightarrow}} \stackrel{C=N}{\underset{C}{\Rightarrow}} \stackrel{OH}{\underset{C}{\Rightarrow}} \stackrel{C=N}{\underset{C}{$\rightarrow}} \stackrel{OH}{\underset{C}{$\rightarrow}} \stackrel{OH}{\underset{C}{$\rightarrow} \stackrel{OH}{\underset{C}{$\rightarrow}} \stackrel{OH}{\underset{C}{$\rightarrow} \stackrel{OH}{\underset{C}{$\rightarrow}} \stackrel{OH}{\underset{C}{$\rightarrow} \stackrel{OH}{\underset{C}{$\rightarrow}} \stackrel{OH}{\underset{C}{$\rightarrow} \stackrel{OH}{\underset{C}{$\rightarrow}} \stackrel{OH}{\underset{C}{$\rightarrow} \stackrel{OH}{\underset{C}{$\rightarrow} \stackrel{OH}{\underset{C}{$\rightarrow} \stackrel{OH}{\underset{C}{$\rightarrow} \stackrel{OH}{\underset{C}{$\rightarrow} \stackrel{OH}{\underset{C}{$\rightarrow} \stackrel{OH}{\underset{C}{$\rightarrow} \stackrel{OH}{\underset{C}{$\rightarrow}$

rolysis in acidic media is a protonation of nitrile and second step is the rate-determining step.

Above pH 7.5, as the case of β -nitrostyrene¹³ the rate of this reaction is proportional to hydroxide ion concentration. Therefore, the mechanism of hydrolysis in basic media is,

$$ArC = C \langle C \equiv N \\ C \equiv N \\ C \equiv N \\ \downarrow \\ C \\ C \equiv N \\ \downarrow \\ Slow \\ C \\ C \\ C \equiv N \\ C \\ C \equiv N \\ C \equiv$$

As shown as Fig. 2 and Table 3, the hydrolysis of DPC is catalized by all base present reaction, however the rate of hydrolysis is not propotional to the concentration of general base. These facts suggest that the reaction mechanism is complicate as the case of β -nitrostyrene¹⁴, and we postulate following reaction mechanism;

$$\begin{array}{c} \operatorname{ArC} = \subset \overbrace{C \equiv N}^{C \equiv N} + \operatorname{H}_{2}O \xrightarrow[k]{H_{2}O} \\ \subset I \\ \operatorname{ArC} = C \\ \subset I \\ \operatorname{C} = N \\ \operatorname{ArC} = C \\ \operatorname{C} = N \\$$

This mechanism was identical with that suggested by Rapoport²¹ in the case of vinyllic substitution of DPC by aromatic amines. The final product, ketone, is identified with 2, 4-

金泰麟・許泰聖

Table 3. pKa and catalytic constant of bases for hydrolysis of DPC at 25 °C.

Base	pKa	$k_1^{\text{H}_2\text{O}}k_2^{\text{B}}/k_{-1}^{\text{H}_2\text{O}}(1/\text{mole}\cdot\text{sec})$
H ₂ O		3.10 × 10 ⁻⁹
CICH2COO-	2.82	8.83 × 10 ⁻⁶
нсоо-	3. 78	2.85×10^{-5}
CH ₃ COO-	4.65	3.56 × 10 ^{-s}
H ₂ PO ₄ -	7.21	1.68 × 10 ⁻³
он-	15.7	285

dinitrophenylhydrazine. Appling steady-state approximation with respect to(V), k_0 is given as following;

$$\frac{1}{k_0} = \frac{1}{k_1} + \frac{1}{k_1/k_{-1}(k_2^{\mathsf{B}}\Sigma(\mathsf{B}))} -$$
(5)

If water and hydroxide ion are the only bases present, equation(5) becomes

$$\frac{1}{k_0} = \frac{1}{k_1} + \frac{1}{k_1/k_{-1}(k_2^{H_2O}(H_2O) + k_2^{OH}(OH^-))}$$
(6)

At high general base concentration, k_0 takes 5. 18×10^{-6} which is the limiting value of general base catalysis in *Fig.* 3. Since at low pH, k_2^{OH} (OH⁻) is negligible compared to the $k_2^{\text{H}_2\text{O}}$. (H₂O), the value of $k_1/k_{-1}(k_2^{\text{H}_2\text{O}}(\text{H}_2\text{O}))$ can be determined from the k_1 and observed rate constant(k_1) and is found to be 3.32×10^{-7} sec⁻¹. The data at pH 5.00 gave the value 2.85×10^{-2} sec⁻¹ for $k_1k_2^{\text{OH}}/k_{-1}$. This measures the efficiency of hydroxide ion as the base catalyst, B, in our mechanism.

The values of the ratio, $k_1^{H_2O} k_2^{E}/k_{-1}^{H_2O}$ calculated by equation (5) and the pKa of the bases are given in *Table* 3 and *Fig.* 4 shows the Brønsted plot. Note that the catalytic constants, k_2 cannot be separated from the hydration equilibrium constant $k_1^{H_2O}/k_{-1}^{H_2O}$.

As the result, if only water and hydroxide ion

are present k_0 becomes

$$\frac{1}{k_0} = \frac{1}{5.18 \times 10^{-6}} + \frac{1}{3.32 \times 10^{-7} + 2.85 \times 10^3 (\text{OH}^-)}$$

$$k_0 = -\frac{1.72 \times 10^{-12} + 1.47 \times 10^{-3} (\text{OH}^-)}{5.51 \times 10^{-6} + 2.85 \times 10^{-2} (\text{OH}^-)}$$
(7)

The nucleophilic addition constant for hydroxide ion $k_{0H}=3.20\times10$ sec⁻¹ is determined from the value of $k_t=3.20\times10^{-4}$ sec⁻¹ at pH 9.00 and $k_t=3.22\times10^{-3}$ sec⁻¹ at pH 10.00

Similarly, the addition constant for hydronium ion $k_{\rm H}$ =5.12×10⁻⁴ is determined. As a result, over-all rate constant becomes

$$k_{i} = 5.12 \times 10^{-4} (\mathrm{H}^{4}) + \frac{1.72 \times 10^{-12} + 1.47 \times 10^{-3} (\mathrm{OH}^{-})}{5.51 \times 10^{-6} + 2.85 \times 10^{2} (\mathrm{OH}^{-})} + 3.20 \times 10^{-} (\mathrm{OH}^{-}) = 5.12 \times 10^{-4} (\mathrm{H}^{+}) + \frac{1.72 \times 10^{-12} + 1.47 \times 10^{-17} / (\mathrm{H}^{4})}{5.51 \times 10^{-6} + 2.85 \times 10^{-12} / (\mathrm{H}^{+})} + 3.20 \times 10^{-13} / (\mathrm{H}^{+})$$
(8)

Fig. 2 and Table 1 show that the values of over all rate constant, k_t calculated by equation (8) and the dotted line represents the contribution of each rate constant. The values of calculated k_t are in good agreement with the observed.

From the rate equation, the mechanism of the hydrolsis of a DFC over wide pH range is fully explained; below pH 3 and above pH 7.5, the rate constant is propotional to the concentration of hydronium ion and hydroxide ion, respectively.

However, in the range of pH 3 to 7.5, water, hydronium ion and hydroxide ion catalyze the hydrolysis of DPC. If acetate ion is present as a general base catalyst, equation (5) becomes

$$\frac{1}{k_{0}} = \frac{1}{k_{1}} + \frac{1}{k_{1}/k_{-1}(k_{2}H_{2}O(H_{2}O) + k_{2}OH(OH^{-}) + k_{2}Ac(Ac^{-}))} = \frac{1}{k_{1}+k_{1}/k_{-1}(k_{2}H_{2}O(H_{2}O) + k_{2}OH(OH^{-}) + k_{2}Ac(Ac^{-}))}{k_{1}(k_{1}/k_{-1}(k_{2}H_{2}O(H_{2}O) + k_{2}OH(OH^{-}) + k_{2}Ac(Ac^{-}))}$$
(9)

Journal of the Korean Chemical Society

434

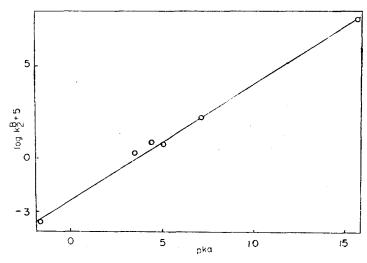

Fig. 4. Brønsted plot for hydrolysis of DPC.

From the values of k_1 , $k_1k_2(H_2O)/k_{-1}$, $k_1k_2^{OH}/k_{-1}$, $(Ac^-)=2.0 \ 10^{-2}$, $(OH^-)=4.47 \ 10^{-10} \ mol/l(pH=4.65)$ and observed rate constant k_i , the value of catalytic constant of acetate ion $k_1k_2^{Ac-}/k_{-1}$ can be determined and is found to be 3.56×10^{-5} .

As the result, equation (9) becomes

$$\frac{1}{k_o} = \frac{1}{5.18 \times 10^{-6}} + \frac{1}{3.32 \times 10^{-7} + 2.85 \times 10^2 \times 4.47}$$
$$\times 10^{-10} + 3.65 \times 10^{-5} (\text{Ac}^-)$$
$$k_o = \frac{2.38 \times 10^{-12} + 1.84 \times 10^{-10} (\text{Ac}^-)}{5.64 \times 10^{-6} + 3.56 \times 10^{-5} (\text{Ac}^-)} \quad (10)$$

Therefore, over-all rate constant becomes

$$k_t = 1. \ 13 \times 10^{-8}$$

$$\therefore \ \frac{2.38 \times 10^{-12} + 1.84 \times 10^{-10} (\text{Ac}^-)}{5.64 \times 10^{-6} + 3.56 \times 10^{-5} (\text{Ac}^-)}$$

$$+ 1.47 \times 10^{-8} \tag{11}$$

Table 2 and Fig. 3 show that the value of over all rate¹¹ constant, k_i calculated by equation(11) are in good agreement with the observed. At low concentration, proton removal is rate controlling and the rate linear in base concentration. As the amount of base becomes large, hydration becomes rate controlling and k_1 approaches the limiting values.

5. Conclusion

1) The kinetics, of the hydrolysis of a DPC over a wide pH range was presented and analyzed in detail. A following rate equation which can be applied over wide pH range_was obtained.

$$k_{t} = 5.12 \times 10^{-4} (\mathrm{H}^{+}) \\ + \frac{1.72 \times 10^{-12} + 1.47 \times}{5.51 \times 10^{-6} + 2.85 \times} \\ \frac{16^{-17} / (\mathrm{H}^{+})}{10^{-12} / (\mathrm{H}^{+})} \\ + 3.20 \times 10^{-13} / (\mathrm{H}^{+})$$

2) From the rate equation the mechanism of a hydrolysis of a DPC over wide pH range is fully explained; below pH 3 and above pH 7.5, the rate constant is proportional to the concentration of hydronium ion and hydroxide ion, respectively. However, in the range of pH 3 to pH 7.5, water, hydronium ion and hydroxide ion are catalyzed the hydrolysis of DPC. Especially from pH 4 to pH 7.5 the mechanism of hydrolysis is very complicated. In this pH range hydroxide ion acts as a catalyst or a nucleophilic reagent.
