Recently the crystal structure of partially $\mathrm{Ag}^{+}$-exchanged zeolite $\mathrm{A}, \mathrm{Ag}_{3.2} \mathrm{Na}_{8.8}-\mathrm{A}$, vacuum dehydrated at $360^{\circ} \mathrm{C}$ and then exposed to 0.1 torr of cesium vapor for 12 hours at $250{ }^{\circ} \mathrm{C}$ has been studied. ${ }^{28}$ In this crystal only $\mathrm{Na}{ }^{+}$ions were also reduced by Cs vapor and replaced by $\mathrm{Cs}^{+}$ions. It appears that $\mathrm{Ag}^{+}$ions are more stable than $\mathrm{Na}^{+}$ions and $\mathrm{Ca}^{2+}$ ion in Cs vapor at $250^{\circ} \mathrm{C}$. But when fully dehydrated, fully $\mathrm{Ag}^{+}$exchanged zeolite A were exposed to 0.1 torr Cs vapor at $250^{\circ} \mathrm{C}$, the resulting crystal showed no single crystal diffraction pattern, indicating that $\mathrm{Ag}^{+}$ions are reduced by Cs vapor and migrated out of zeolite frameworks. ${ }^{8}$ This exchange reaction using metal vapor may be viewed as a way of achieving ion exchange without the use of a solvent. This method of ion exchange allows problems of hydrolysis and overexchange to be circumvented. These problems are often encounter when ion exchange from aqueous solution is attempted.

# The Molecular Structure and Conformational Stability of Cyclobutylmethyl Ketone by MM2 

Mu Sang Lee* and Young Mee Jung<br>Department of Chemistry, Teachers College, Kyungpook National University, Taegu 702-701<br>Received January 12, 1989

#### Abstract

The molecular structure of cyclobutylmethyl ketone ( ( $-\mathrm{C}_{4} \mathrm{H}_{7} \mathrm{COCH}_{3}$ ) has been investigated by molecular mechanics II (MM2). For the monosubstituted cyclobutane there are two possible ring conformations, the equatorial and axial form, but for the cyclobutylmethyl ketone the equatorial form is predominant conformation. For the $\mathrm{COCH}_{3}$ moiety there are two stable orientations which are the equatorial-gauche and the equatorial-trans form. The equatorial-gauche form where the $\mathrm{C}=\mathrm{O}$ bond is nearly eclipsing (torsional angle $\angle \mathrm{C} 4-\mathrm{C} 3-\mathrm{C} 2-\mathrm{O} 10=14.5^{\circ}$ ) one of the $\alpha \mathrm{C}-\mathrm{C}$ bonds of the four-membered ring was preferred conformer with steric energy of $13.37 \mathrm{kcal} / \mathrm{mol}$. The equatorial-trans form where the $\mathrm{C}=0$ bond is nearly eclipsing ( $\angle \mathrm{C} 4-\mathrm{C} 3-$ $\mathrm{C} 2-\mathrm{O} 10=145.0^{\circ}$ ) the $a \mathrm{C}-\mathrm{H}$ bond of the four-membered ring was less stable conformer with steric energy of $15.40 \mathrm{kcal} / \mathrm{mol}$.

## Introduction

Previous works by several groups have shown that halo-
cyclobutanes similar with cyclobutylmethyl ketone exist only as a equatorial conformer. ${ }^{1-7}$

For cyclobutylmethly ketone two conformers, equato-
rial-gauche and equatorial-trans, have been studied with IR and Raman spectra. Durig et al. reported ${ }^{8}$ that the molecular existed predominantly the equatorial-gauche conformation (the $\mathrm{COCH}_{3}$ group is in the equatorial position relative to the four-membered ring with the $\mathrm{C}=0$ nearly eclipsing one of the C-C bonds of ring) in the gaseous and liquid states and exclusively in this conformation in the solid state based on the band contours in the IR spectrum. By Raman spectra of the fluid phases, they also reported that a second conformer is present at ambient temperature and this conformer is believed to be equatorial-trans where the $\mathrm{C}=0$ is eclipsing the a CH bond of the four-membered ring.

But detailed molecular structure has not yet been reported. In this paper we have calculated the molecular structure and conformational stability of cyclobutylmethyl ketone by the molecular mechanics computer program, MM2. ${ }^{9}$

## Theory

The molecular mechanics method is now being used to an ever increasing extent by chemist to calculate geometric, spectroscopic, and thermodynamic properties of organic molecules. Since the predicted values by molecular mechanics method often approach experimental accuracy and can be obtained much faster and more easily than experimental measurements. ${ }^{00-14}$

In molecular mechanics, a molecule is considered to be a collection of atoms held together by elastic and harmonic forces. These forces can be described by potential energy functions of structural features like bond lengths, bond angles, nonbonded interaction, and so on. The combination of these potential energy function is the force field. ${ }^{15.16}$

Steric energy is the difference in energy between the real molecule and a hypothetical molecule where all the structual values are exactly at their ideal or natural values. ${ }^{16}$

The steric energy of molecule, then relative to an arbitrary natural point is so far given by equation (1).

$$
\begin{equation*}
E=E_{s}+E_{\theta}+E_{v d w}+E_{w} \tag{1}
\end{equation*}
$$

In equation (1), $E_{s}$ is the stretching energy, $E_{\theta}$ is the bending energy, $E_{\text {vedw }}$ is the van der Waals interaction ${ }^{17}$ and $E_{\omega}$ is the torsional energy

The basis for the energy minimization scheme is as follows. ${ }^{12,16,18}$ The structure of the molecule will correspond to that geometry where the energy is at a minimum. It is assumed that the energy surface in the vicinity of an energy mi nimum can be approximated by the equation (2), where $x, y$ and $z$ represent the cartesian coordinates of the atom in equation, and $A-J$ have numerical values that one wants to determine.

$$
\begin{equation*}
E=A x^{2}+B y^{2}+C z^{2}+D x y+E y z+F x z+G x+H y+I z+J \tag{2}
\end{equation*}
$$

A necessary condition for an energy minimum is that the partial derivatives of the energy with respect to each coordinate equal to zero. If we take our initial structure, and work on one atom at a time, what we need to do is to differentiate the above equation with respect to $x, y$ and $z$ and set each of the resulting equations equal to zero, and iterate over all atoms. We can therefore apply this procedure in turn to the individual atoms, and then keep on applying it and approach the

gives the several of bond length, bond angle and dihedral angle data among the results of these calculation for the equatorial-gauche conformer.

The calculated dihedral angle data show the detailed molecular structure. The most stable structure was the equa-torial-gauche conformer with the dihedral angle ( $\angle \mathrm{C} 4-\mathrm{C} 3-$ $\mathrm{C} 2-\mathrm{O} 10$ ) of $14.5^{\circ}$. In Table 2, the calculated dihedral angle ( $\angle \mathrm{C} 4-\mathrm{C} 3-\mathrm{C} 2-\mathrm{O} 10$ ) of the equatorial-trans conformer was $145.0^{\circ}$.

The several of van der Waals energy data among the nonbonded interactions are shown in Table 3.

The steric energies of the calculated results with changing the torsional angle of every 10 degree against the rotating axis C2-C3 are shown in Table 4.

Figure 2 is a plot of the calculated steric energy as a func-

Figure 2. Steric energy (Kcal/mol) as a function of the torsional angle.

| 249 | 13.62 | 260 | 13.90 |
| 250 | 13.63 |  |  |

tion of the torsional angle ( $\angle \mathrm{C} 4-\mathrm{C} 3-\mathrm{C} 2-\mathrm{O} 10$ ). When the torsional angle was $14.5^{\circ}$ the steric energy had minimum value. Therefore, the equatorial-gauche conformer which had the torsional angle of $14.5^{\circ}$ was the most stable structure. Another less stable conformer was the equatorial-trans conformer when the torsional angle was $120^{\circ}$ or $150^{\circ}$. In Figure 2 , cyclobutylmethyl ketone has three minimum energy values with the torsional angle of $14.5^{\circ}, 145^{\circ}$ and $245^{\circ}$. However the torsional angle of $14.5^{\circ} 245^{\circ}$ have nearly equivalent value of the steric energy so that the two conformer is the same structure. Theoretically the conformer with the torsional angle of about $255.5^{\circ}$ is the same structure with the torsional angle of $14.5^{\circ}$ by symmetrical coordinations since the torsional angles of $\mathrm{C} 4-\mathrm{C} 3-\mathrm{C} 2-\mathrm{O} 10$ and $\mathrm{C} 6-\mathrm{C} 3-$ $\mathrm{C} 2-\mathrm{O} 10$ are symmetrically equivalent angle positions. But the calculated results shows the conformer with the torsional angle of $245^{\circ}$ has minimum energy. The energy difference between the torsional angle ( $245^{\circ}$ and $255^{\circ}$ ) is 0.16 $\mathrm{Kca} / \mathrm{mol}$. Therefore this conformer can exist between the torsional angle of $240^{\circ}$ and $255^{\circ}$. The calculated steric energies with changing the torsional angle of every 1 degree are given in Table 5.

To identify detailed structure of the equatorial-trans conformer we calculated steric energies with changing the torsional angle every 5 degree in the double minimum region (from $110^{\circ}$ to $150^{\circ}$ ) of Figure 2. The results of this calculation are given in Table 6. In Table 6, when the torsional

| $\cdots-$ | 15.40 |
|  | 150 |

Figure 3. Steric energy (Kcalmol) as a function of the torsional angle.
angle was $145^{\circ}$ the steric energy was the smallest. A plot of the calculated steric energy as a function of the torsional angle is shown in Figure 3. The steric energy difference between the torsional angle of $120^{\circ}$ and $145^{\circ}$ is $0.08 \mathrm{Kca} / \mathrm{mol}$. The energy barrier between the torsional angle of $130^{\circ}$ and $145^{\circ}$ is only $0.14 \mathrm{Kca} / \mathrm{mol}$. Consequently the equatorialtrans conformer can exist between $120^{\circ}$ and $145^{\circ}$ of the torsional angle.

## Conclusion

Each conformation of cyclobutylmethyl ketone was
characterized by the calculated torsional angle.
The steric energy of the most stable equatorial-gauche conformer with the torsional angle of $14.5^{\circ}$ was 13.37 Kcal mal. The second stable equatorial-trans conformer with the torsional angle of $145.0^{\circ}$ was $15.40 \mathrm{Kcal} / \mathrm{mol}$.

The steric energy differences of the two conformer was $2.03 \mathrm{Kcal} / \mathrm{mol}$ and was consistent with the IR and Raman experimental data. ${ }^{8}$
