# ON ENDOMORPHISM RING OF H-INVARIANT MODULES* 

Soon-Sook Bae

## O. ABSTRACT

The relationships between submodules of a module and ideals of the endomorphism ring of a module had been studied in (1). For a submodule $L$ of a moudle $M$, the set $I^{L}$ of all endomorphisms whose images are contained in $L$ is a left ideal of the endomorphism ring End $(M)$ and for a submodule N of M , the set $\mathrm{I}_{\mathrm{N}}$ of all endomorphisms whose kernels contain N is a right ideal of End(M).

In this paper, author defines an H -invariant module and proves that every submodule of an H -invariant module is the image and kernel of untique endomorphisms. Every ideal $\mathrm{I}^{L}\left(\mathrm{I}_{\mathrm{N}}\right)$ of the endomorphism ring End(M) when $M$ is $H$-invariant is a left(respectively, right) principal ideal of End(M). From the above results, if a module M is H -invariant then each left, right, or both sided ideal I of End(M) is an intersection of a left, right, or both sided principal ideal and I itself appropriately. If M is an H -invariant module then the ACC on the set of all left ideals of type $\mathrm{I}^{2}$ implies the ACC on M . Also if the set of all right ideals of type $I_{4}$ has DCC, then $H$-invariant module $M$ satisfies ACC. If the set of all left ideals of type $\mathrm{I}^{\mathrm{L}}$ satisfies DCC, then H -invariant module M satisfies DCC.

[^0]If the set of all right ideals of type $\mathrm{I}_{\mathrm{N}}$ satisfies ACC then H -invariant module M satisfies DCC . Therefore for an H -nvariant module M , if the endomorphism ring End(M) is left Noetherian, then M satisfies ACC. And if End(M) is right Noetherian then M satisfies DCC. For an H-invariant module M, if End (M) is left Artinian then M satisfies DCC. Also if End (M) is right Artinian then $M$ satısfies ACC.

## 1. INTRODUCTION

Every ring is assumed to be an assoclative ring with an identity and every module to be a left module over a ring.

For an element a of nimg $R,{ }^{1}(a)=R a+Z a$ means the left ideal generated by a. Also $\quad(\mathrm{a})=\mathrm{aR}+\mathrm{Za}$ means the right ideal generated by a and $(a)=1(a)+r(a)+R a R$ means the ideal generated by a in a ring $R$.
The ring of $R$-endomorphisms of a left R -module ${ }_{\mathrm{R}} \mathrm{M}$, denoted by End ( ${ }_{R} \mathrm{M}$ ), will be written on the right side of ${ }_{\mathrm{R}} \mathrm{M}$ as right operators on ${ }_{\mathrm{R}} \mathrm{M}$, that is, $\left.{ }_{\mathrm{R}} \mathrm{M}_{\text {End }(\mathrm{M}} \mathrm{M}\right)$ will be considered on this paper. For a submodule L of a left $R$-module ${ }_{R} M$, the subset $\left\{f \varepsilon E n d\left({ }_{R} M\right) \mid \operatorname{Imf} \leq L\right\}$ and the subset $\left\{f \varepsilon E n d\left({ }_{R} M\right) L \leq \operatorname{kerf}\right\}$ of the endomorphism ring End $\left(_{R} M\right)$ will be denoted by $\mathrm{I}^{1}, \mathrm{I}_{\mathrm{L}}$ respectively. Then $\mathrm{I}^{\mathrm{L}}$ and $\mathrm{I}_{\mathrm{L}}$ become to be a left and a right ideal of $\operatorname{End}\left({ }_{k} M\right)$ respectively.

Especially, if L is a fully invariant submodule of a module M , then $\mathrm{I}^{\text {' }}$ and $\mathbf{I}_{L}$ turn out to be both sided ideals of $\operatorname{End}(\mathrm{M})$. Thus for two fully invariant submodules $L, N$ of a module $M$, we have a both sided ideal $\mathrm{I}_{\mathrm{N}}^{\mathrm{L}}=\mathrm{I}^{2} \cap \mathrm{I}_{\mathrm{N}}$, which will be studied. Every right ideal I of End(M) is contained in the right ideal $\mathrm{I}_{\mathrm{v}}$ where $\mathrm{N}=\bigcap_{\mathrm{I}}$ kerf.
Especially if such N is the kernel of an endomorphism, say g , then $I_{\mathrm{N}}=\mathrm{r}(\mathrm{g}) \cap \mathrm{I}$. Moreover if such $\mathrm{N}=$ kerg is fully invariant in M , then $\mathrm{I}_{\mathrm{N}}=(\mathrm{g})$ $\cap \mathrm{I}$ in $\operatorname{End}(\mathrm{M})$. A left R-moduel ${ }_{\mathrm{R}} \mathrm{M}$ is said to be free if it is a sum of copies of R.

Theorem. (p57, (12]) Let $X=\left\{a_{i} \mid i \varepsilon A\right\}$ be a basis of a free module M. Given any module $B$ and any function $f: X \rightarrow B$ there exists a unique homomorphism $\mathrm{f}: \mathrm{M} \rightarrow \mathrm{B}$ extending f .

In a free module M with a basis X , for underlying set UM (forget addition and scalar multiplication) there is a free module with basis UM. Hence basis X is a subset of UM so that there is a unique homomorphism $\mathrm{j}: \mathrm{M} \rightarrow \mathrm{FUM}$ extending the inclusion $\mathrm{X} \rightarrow \mathrm{FUM}$ since M is free

Hence we need a definition of an H -invariant module such that such $j$ is an inclusion. A free module ${ }_{\mathrm{R}} \mathrm{M}$ is said to be H -mvariant if there is an inclusion R-homomorphism from ${ }_{\mathbf{R}} \mathrm{M}$ into FUM

From this definition every submodule of an H -invariant module is an image of a unique endomorphism and a kernel of a unique endomorphism. Hence in an H -invariant module M , for each submodule $\mathrm{L}, \mathrm{I}^{\mathrm{L}}$ is a left principal ideal of $\operatorname{End}(M), I_{L}$ is a right principal ideal of End(M). Since every H-invariant module is projective (proposition 2, p82[9]) in
an H -invanant module M , every epimorphism is left invertible in End (M). Thus if $L$ is a small submodule of $M$, then the left ideal $I^{L}$ is a small left ideal of End (M) and if N is a large submodule of an H -invariant module $M$, then the right ideal $I_{v}$ is small in End (M), In an $H$-invariant module if I is a left ideal of End $(M)$, then $I=l(f) \cap I$ for a unique endomorphism $f$ such that $\sum_{g \in I} \operatorname{Img}=\operatorname{Imf}$. For a right idal I of End (M), we have $I=r(f) \cap I$ for a unique endomorphism $f$ such that $\bigcap_{g \in I}$ kerg $=$ kerf. Hence, since two sided ideal I has two fully invariant submodule $L=\sum_{g \in L} \operatorname{Img}=I m h$ and $\cap_{g \in I} \operatorname{kerg}=N=k e r f$ for unique endomorphisms $h, f$ in End (M) we have that $I=(h) \cap(f) \cap I$. For two fully invariant submodules $\mathrm{L}, \mathrm{N}$ of an H -invariant module, we have a both sided ideal $I \frac{1}{\mathrm{~A}}=(\mathrm{I}) \mathrm{I}^{\prime}(\mathrm{g})$, wherer $\mathrm{L}=\operatorname{lmf}$ and $\mathrm{N}=$ kerg for unique endomorphisms $f, g$ in End(M). In last section author invest these results to study the relationship between the ACC (ascending chain condition), DCC(descending chain condition) on H -invanant module left Noetherian, right Noetherian, right Artinian, left Artinian endomorphism ring. If ${ }_{\mathrm{r}} \mathrm{M}$ satisfies $A C C$, then the set of all rdeals of type $I^{l}$ satisfies $A C C$ and the set of ideals of type $I_{N}$ satisfies DCC. If $M$ satisfies $D C C$, then the set of all ideals of type $I^{+}$satsfies DCC and the set of all ideals of type $I_{N}$ satisfies ACC. In an H-invariant module the partial converse holds. If the set of all ideals of type $\mathrm{I}^{\mathrm{L}}$ satisfies ACC or the set of all ideals of type $\mathrm{I}_{4}$ satisftes DCC then H -invariant module M satisfies ACC . If End (M) is left Noetherian, then the set of all ideals of type $I^{2}$ satisfies ACC, and hence H -invariant module M satisfies ACC. Consequently, if End(M) is left Noetherian, then H-invariant module $M$ satisies ACC. The similar results are discussed in this paper.

## 1. H-INVARIANT MODULE

A left R -module ${ }_{\mathrm{R}} \mathrm{M}$ is said to be free if it is a sum of copies of R .

For any set $X$, there exists a free module $A$ having $X$ as a basis.

Theorem 1.1. (p57(12]) Let $X=\left\{a_{1} \mid i \varepsilon I\right\}$ be a basis of a free module A. Given any module $B$ and any function $f: X \rightarrow B$ there is a unique $R$ homorphism $f: A \rightarrow B$ extending $f$.

Remark 1.2. In a free module ${ }_{\mathrm{R}} \mathrm{M}$ with a basis X , let UM be the underlying set of M (forget addition and scalar multiphcation), then we have the (up to isomorphism) free module FUM with basis UM. We know that basis X is a subset of UM, and UM is a subset of FUM. Thus the inclusion mapping $\mathrm{i}: \mathrm{X} \rightarrow \mathrm{FUM}$ exists. If M is a free module, then we have a unique R-homomorphism J:M $\rightarrow$ FUM. But such j need not to be an inclusion. hence we need the following definition.

Definition. 1.3. A free R -module ${ }_{\mathrm{R}} \mathrm{M}$ is satd to be H -invariant if there is an inclusion R-homomorphism $\mathbf{j}: \mathrm{M} \rightarrow$ FUM where FUM is the free R -module generated by the underlying set UM of ${ }_{\mathrm{R}} \mathrm{M}$

Remark 1.4. Since every free module is projective, every epimorphism is left invertible. Hence in an H -invarant module every epmorphism in the endomorphism ring is left invertible But not every free module need be injective and not every free module need be H -invariant, H -invariantness is not a sufficient condition to be injective.

But we have the following result, every monomorphism is right inver-
tible in endomorphism ring of an H -invariant module.

Theorem 1.5. In an H -invariant module ${ }_{\mathrm{k}} \mathrm{M}$, every monomorphism in End $\left({ }_{R} M\right)$ is invertible.

Proof. Let $f$ be any monomorphism in $\operatorname{End}\left({ }_{R} M\right)$ then consider a diagram

As a set map $f$ has a right inverse $\mathrm{f}^{\prime}$ such that $\mathrm{ff}^{\prime}=1$ For such $\mathrm{f}^{\prime}$ there exists a unique $R$-homomorphism $f^{\prime}$ extending $f^{\prime}$ so we have an R-endomorphism $\mathrm{jf}^{\prime}: \mathrm{M} \rightarrow \mathrm{M}$ such that $\mathrm{fjf}^{\prime}=1$. Hence f is right invertible in End $\left({ }_{R} M\right)$. Since $j$ is an inclusion $R$-homomorphism from $H$-invariantness of ${ }_{\mathrm{R}} \mathrm{M}$.

Theorem 1.6. If L is a small submodule of an H -invariant module ${ }_{\mathrm{R}} \mathrm{M}$, then the left ideal $I^{1}$ is small in End( ${ }^{1} M$ ).

Proof. This easily follows from the similar way of proof Theorem 4.4 in (17) and using that every epomorphism is right invertble.

Theorem 1.7. If N is a large submodule of an H -nvariant ${ }_{\mathrm{k}} \mathrm{M}$, then the right ideal $I_{N}$ is small in $\operatorname{End}\left({ }_{R} M\right)$.

Proof. This easily follows from the same way in proof of Theorem 5.4 in (17) and using Theorem 1.5.

Theorem 1.8. For any submodule L of an H -invariant module ${ }_{\mathrm{k}} \mathrm{M}$, there is a unique endomorphism $f \varepsilon E n d\left({ }_{k} M\right)$ such that $L=\operatorname{Imf}$

Proof. Define $C_{L}: U M=M \rightarrow M$ by $\mathrm{xC}_{\mathrm{L}}=\left\{\begin{array}{l}\mathrm{x} \text { if } \mathrm{x} \mathrm{\varepsilon L} \\ 0, \text { otherwise. }\end{array}\right.$
Then we have a diagram in which there is a unque R -homomorphism $\varphi:$ FUM $\rightarrow \mathrm{M}$ such that $\mathrm{C}_{\mathrm{L}}=1 \mathrm{j} \varphi=\mathrm{j} \varphi$ (note the composition map $\mathrm{j} \varphi$ is an R -homomorphism). Hence $\mathrm{ImC}_{\mathrm{L}}=\mathrm{L}=\mathrm{Imj} \varphi$. Once we had regarded an H invariant module ${ }_{\mathrm{k}} \mathrm{M}$ as a submodule of a free module FUM then the composition $\mathrm{j} \varphi$ is unique. Hence $\mathrm{L}=\mathrm{Imj} \varphi$. $\mathrm{f}=\mathrm{j} \varphi$ is the required one.

Theorem 1.9. For any submodule L of an H -invariant module ${ }_{\mathrm{R}} \mathrm{M}$, the left ideal $I^{\mathrm{L}}$ is proncipal in $\operatorname{End}\left({ }_{R} M\right)$.

Proof. Since every free module is projective (Proposition) 2, p82(9]) and since $\mathrm{L}=\mathrm{Imf}$ for a unique $f \mathrm{EEnd}\left({ }_{\mathrm{R}} \mathrm{M}\right)$ by Theorem 1.8. $\mathrm{I}^{\text {L }}={ }^{1}(f)$ by Theorem 4.7 in (17)

Corollary $\mathbf{1 . 1 0}$. For any fully invariant submodule L of an H -invariant module ${ }_{\mathrm{R}} \mathrm{M}$, the both sided ideal $\mathrm{I}^{\mathrm{L}}$ is principal in $\operatorname{End}\left({ }_{\mathrm{R}} \mathrm{M}\right)$.

Proof. By Corollary 4.8 in \{17\} and Theorem $1.10 \mathrm{I}^{2}=$ (f) for a unique endomorphism.

Theorem 1.11. Let I be a alleft ideal of $\operatorname{End}\left({ }_{k} M\right)$ for an $H$-invariant module ${ }_{\mathrm{R}} \mathrm{M}, \mathrm{I}={ }^{1}(\mathrm{f}) \cap \mathrm{I}$ for a unique endomorphism f .

Proof. Let $\mathrm{L}=\sum_{\text {, } \in \mathrm{I}}$ Imi. Then there is a unique endomorphism f such that $L=I m f$ by Theorem 1.8. From (1) 1.1, in (17) $I \leq I^{\llcorner }$and from Theorem $1.10, \mathrm{I}^{L}={ }^{1}(\mathrm{f})$, we have $\mathrm{I}={ }^{1}(\mathrm{f}) \cap \mathrm{I}$.

Corollary 1.12. Let I be a both sided ideal of $\operatorname{End}\left({ }_{R} M\right)$ for an H -invanant module ${ }_{\mathrm{R}} \mathrm{M}$. Then $\mathrm{I}=(\mathrm{f}) \cap \mathrm{I}$ for a unique $\mathrm{f} \varepsilon \mathrm{End}^{( }{ }_{\mathrm{R}} \mathrm{M}$ ).

Proof. By Remark 23. $\operatorname{in}(17) \mathrm{L}=\sum_{i \in 1}$ Imi is a fully invariant submodule of an H-invariant module ${ }_{\mathrm{R}} \mathrm{M}$. By Corollary 1.10. and similar computation in Corollary 1.11. we have $I=(f) \cap I$ for a unique endomorphism $f$.

Theorem 1.13. For any submodule N of an H -invariant module ${ }_{\mathrm{R}} \mathrm{M}$, there is a unique endomorphism $\operatorname{g\varepsilon End}\left({ }_{\mathrm{R}} \mathrm{M}\right)$ such that $\operatorname{kerg}=\mathrm{N}$.

Proof. Define $\mathrm{C}_{\mathrm{M}-\mathrm{N}}: \mathrm{UM}=\mathrm{M} \rightarrow \mathrm{M}$ by $\mathrm{x}_{\mathrm{M}-\mathrm{N}}=\mathrm{x}_{1}$ if $\mathrm{x} \varepsilon \mathrm{M}-\mathrm{N}$
Then we have a dragam, where $\mathrm{M}-\mathrm{N}=\{\mathrm{x} £ \mathrm{M} \mid \mathrm{x} \notin \mathrm{N}\}$,

in which there is a unique R-homomorphism $\varphi: \mathrm{FUM} \rightarrow \mathrm{M}$ such that $C_{i n-n}=10 \rho=j \varphi$ (here, the coniposition $j \varphi$ is an $R$-homomorphism). Hence $\left\{x \in M \mid x_{M-x}=0\right\}=\operatorname{kerj} \varphi=N$. The composition $g=j \varphi$ is the required endomorphism.

Theorem 1.14. For any submodule N of an H -invariant module ${ }_{\mathrm{g}} \mathrm{M}$, the right ideal $\mathrm{I}_{N}$ is a right principal ideal of $\operatorname{End}\left({ }_{\mathrm{R}} \mathrm{M}\right)$.

Proof. By Theorem 1.13, there is a unique endomorphism $g$ such that $\mathrm{N}=$ kerg. If $\mathrm{fel}_{\mathrm{N}}$ is given arbitrarily, then we clam that $\mathrm{f}=\mathrm{gh}$ for some endomorphism $\mathrm{h}: \mathrm{M} \rightarrow \mathrm{M}$.

Let $\mathrm{f}, \mathrm{g}: \mathrm{M} / \mathrm{N} \rightarrow \mathrm{M}$ be defined by $(\mathrm{x}+\mathrm{N}) \mathrm{f}=\mathrm{xf}$ and $(\mathrm{x}+\mathrm{N}) \mathrm{g}=\mathrm{xg}$ for all $x+N$ in $M / N$. Then for the projection $\pi: M \rightarrow M / N$, we have $\pi f=f$ and $\pi g=g$ Since $N=$ kerg $\leq$ ker $f$ which implies that $f$ and $g$ are well defined on $\mathrm{M} / \mathrm{N}$. Considering a diagram where g 'is denoted by a right inverse map of a 1-to-1 map $\bar{g}$ since as a set map, every one-to-one map has a right inverse.

And let $\underline{h}=g^{\prime} f$, then $\mathrm{f}=\mathrm{gh}=\mathrm{gg}^{\prime} \mathrm{f}$ and for such $\underline{h}$ there is a unique R -

homomorphism $\mathrm{h}: \mathrm{FUM} \rightarrow \mathrm{M}$ extending h . As a map $\pi \mathrm{f}=\mathrm{f}=\pi \mathrm{g} 1 \mathrm{jh}=\mathrm{gh}$ when $\mathrm{h}=1 \mathrm{jh}=\mathrm{gh}$ when $\mathrm{h}=1 \mathrm{jh}=\mathrm{jh}$ is taken.

Therefore $\mathrm{f}=\mathrm{gh}$. Hence $\mathrm{I}_{\mathrm{N}}=\mathrm{r}(\mathrm{g})$ which is a right principle ideal of End ( ${ }_{\mathrm{k}} \mathrm{M}$ ).

Coroliary 1.15. For any fully invariant submodule N of an H -invariant

Proof. By the above theorem, $\mathrm{I}_{N}=(\mathrm{g})$ for a unique endomorphism $\operatorname{geEnd}\left({ }_{\mathrm{R}} \mathrm{M}\right)$.

Theorem 1.16. Let I be any right ideal of $\operatorname{End}\left({ }_{R} M\right)$ for an H -invariant

Proof. Let $\mathrm{N}=\bigcap_{\in \in}$ keri. Then there exists a unique endomorphism $g \varepsilon$
End ${ }^{\mathrm{R}} \mathrm{M}$ ) such that $\mathrm{N}=$ kerg, by Theorem 6.11.
By (1) 2.2 in $\{17\} \mathrm{I} \leq \mathrm{I}_{\mathrm{N}}$ and by Theorem 1.14, $\mathrm{I}_{\mathrm{N}}=\mathrm{I}(\mathrm{g})$ so we have $\mathrm{I}=\mathrm{I}_{\mathrm{N} \cap} \cap \mathrm{I}={ }^{\mathrm{r}}(\mathrm{g}) \cap \mathrm{I}$.

Theorem 1.17 In an H -invariant module ${ }_{\mathrm{k}} \mathrm{M}$, if I is a both sided ideal of $\operatorname{End}\left({ }_{k} M\right)$, then there exist $f, g \varepsilon E n d\left({ }_{k} M\right)$ such that $I=(f) \cap(g) \cap I$, uniquely.

Proof. From Remarks 1.4 and 2.3 in \{17), every both sided ideal I has two fully invariant submodules $L=\sum_{i \in I}$ Imi and $N=\bigcap_{\in \in I}$ keri. Now we have two unique endomorphisms $\mathrm{f}, \mathrm{g} \in \mathrm{End}\left({ }_{k} \mathrm{M}\right)$ such that $\mathrm{L}=\operatorname{Imf}$ and $\mathrm{N}=$ kerg by Theorem 1.8 and 1.13. Thus $\mathrm{I}=\mathrm{I}_{\mathrm{N}}^{\mathrm{L}} \cap \mathrm{I}=\mathrm{I}^{\mathrm{L}} \cap \mathrm{I}_{\mathrm{N}} \cap \mathrm{I}=(\mathrm{f}) \cap(\mathrm{g}) \cap \mathrm{I}$ is followed.

Corollary 1.18. Let ${ }_{\mathrm{R}} \mathrm{M}$ be an H -invariant module. Then for two fully invariant submodules $L$, $N$ the both sided ideal $I_{N}^{⿺}=(f) \cap(g)$ for unique endomorphisms f, g in $\operatorname{End}\left({ }_{\mathrm{R}} \mathrm{M}\right)$.

Proof. By Theorems 1.8 and $1.13, \mathrm{~L}=\mathrm{Imf}$ and $\mathrm{N}=$ kerg for unique endomorphisms f, g, in $\operatorname{End}\left({ }_{\mathrm{R}} \mathrm{M}\right)$. Hence by Corollaries 1.10 and 1.15, $\mathrm{I}_{\mathrm{N}}^{\mathrm{L}}=\mathrm{I}^{\mathrm{L}} \cap \mathrm{I}_{\mathrm{N}}=(\mathrm{f}) \cap(\mathrm{g})$.

Corollary 1.19. Let ${ }_{\mathrm{k}} \mathrm{M}$ be an H -invariant module and let I be a subset of $\operatorname{End}\left({ }_{\mathrm{R}} \mathrm{M}\right)$. Then we have the following
(1) if $I$ is a left ideal, then $I=^{1}(f) \cap(g) \cap I$
(2) if $I$ is a right ideal, then $I=(f) \cap^{\prime}(g) \cap I$
 $\mathrm{f}, \operatorname{geEnd}\left(\mathrm{R} \mathrm{M}^{\mathrm{M}}\right)$.

Proof. By Theorems 1.8 and 1.13 , the existences of $f, g$ in $\operatorname{End}\left({ }_{k} M\right)$ are guaranteed such that $L=\operatorname{Imf}$ and $N=$ kerg.
By Remark $1.4 \mathrm{~m}(17)$ for a left ideal $\mathrm{I}, \mathrm{N}$ is a fully invariant submodule. Hence we have (1) $\mathrm{I}^{1}(\mathrm{f}) \cap(\mathrm{g}) \cap \mathrm{I}$. similarly for a right sided ideal $\mathrm{I}, \mathrm{L}$ is a fully invariant submodule of ${ }_{\mathrm{R}} \mathrm{M}$ hence we can conclude that $\mathrm{I}=(\mathrm{f}) \cap^{\prime}(\mathrm{g}) \cap \mathrm{I}$.

## 2. MODULE WITH CHAIN CONDITION (ACC/DCC)

A module M is said to satisfy the ascending chain condition(ACC) on submodules (or to be Noetherian) if every chain $L_{1} \leq L_{2} \leq L_{3} \leq \cdots \cdots$ of submodules of $M$, there is an integer $n$ such that $L_{n}=L_{r}$ for all $\mathrm{i} \geq \mathrm{n}$.〔7〕. A module M is said to satisfy the descending chain condition(DCC) on submodules (or to be Artinian) if for every chain $N_{1} \geq N_{2} \geq N_{3} \geq \ldots \ldots$. of submodules of $M$, there is an integer $m$ such that $N_{c}=N_{m}$ for all $i \geq$ m.

A ring $R$ is left(resp. right) Noetherian of $R$ satisfies $A C C$ on left(resp. right) ideais. $\bar{R}$ is said to be Notherran if $\bar{R}$ is both left and rght Noetherian. A ring $R$ is left(resp. right) Artmian if $R$ satisfies the DCC on left(resp. right) ideals. $R$ is said to be Artinian if $R$ is both left and right Artinian.

But it is still hard to say that ACC on a module $M$ is possible to imply ACC on the endomorphism ring End ( ${ }_{\mathrm{R}} \mathrm{M}$ ). For certain module, namely an H -invariant module, the converse holds, in other words, if M is H -invariant then ACC on End(M) implies ACC on submodules of M. We are going to prove this gradually.

Lemma 2.1 In an H-invariant module, if L and L ' are distinct submodules of M , then the left ideals $\mathrm{I}^{\mathrm{L}}$ and $\mathrm{I}^{\mathrm{L}}$ are distinct in End(M).

Proof. In an H-invariant module M , by Theorem $1.8, \mathrm{~L}=\operatorname{Imf}$ and L $=\operatorname{Img}$ for unique endomorphisms $\mathrm{f}, \mathrm{g} \varepsilon$ End(M). Suppose the left ideals $I^{L}$ and $I^{L}$ are equal. Then $f \varepsilon I^{L}=I^{L}$ says that $L=I m f \leq L^{\prime}$ thus we have $\mathrm{L} \leq \mathrm{L}$ '. similar argument says that L ' $\leq \mathrm{L}$. Hence $\mathrm{L}=\mathrm{L}$ ' which is contradicted.

Lemma 2.2 In an H-invariant module M, two distinct submodules $N$, $N^{\prime}$ have distinct right ideals $\mathrm{I}_{k} \mathrm{I}_{\mathrm{N}}$, respectively.

Proof. In an H-invariant module, by Theorem 1.13, for submodules N , $N$ 'of a module $M$, there are unique endomorohisms $f$, $g$ such that $N=$ kerf, $N^{\prime}=$ kerg. Suppose that the right ideais $I_{r}$ and $I_{N}$ are equal. Then $\mathrm{f} \varepsilon \mathrm{I}_{N}=\mathrm{I}_{\mathrm{N}}$ implies that $\mathrm{N}^{\prime} \leq$ kerf $=\mathrm{N}$ and $\mathrm{g} \varepsilon \mathrm{I}_{\mathrm{N}}=\mathrm{I}_{\mathrm{v}}$ imphes that $\mathrm{N} \leq \mathrm{kerg}$ $=\mathrm{N}^{\prime}$ Thus $\mathrm{N}=\mathrm{N}^{\prime}$

Remark 2.3. In an H -invariant module M , if $\mathrm{L} \neq \mathrm{L}^{\prime}$, then $\mathrm{L}^{\mathrm{L}} \neq \mathrm{I}^{\mathrm{L}^{\prime}}$, and also if $\mathrm{N}_{\neq \mathrm{N}^{\prime}}$ then $\mathrm{I}_{\mathrm{v}} \neq \mathrm{I}_{\text {, }}$.

Note 2.4. Without H-invariantness of a module M , the above Lemma 2.1 and 22 don't have to have these properties. For an example let M $=R$ the set of all reais, $Q$ the set of all rationals, and $Z$ the set of all integers. Then R is not an H -invariant (since R is not free) module over $Z$ and $\mathrm{I}^{\mathrm{Q}}=\mathrm{I}^{7}=0$ even though $\mathrm{Z} \leq \mathrm{Q}$. And $\mathrm{I}_{\mathrm{Q}}=\mathrm{I}_{2}=0$.

Theorem 2.5 Let M be an H -invariant module and the set $\left\{\mathrm{I}^{\mathrm{L}} \mid \mathrm{L} \leq\right.$ M\} satisfy the ACC. then M satısfies ACC.

Proof. Let $L_{1} \leq L_{2} \leq L_{3} \cdots \cdots$ be any ascending chan of submodules of $M$. Then we have an ascending chain $\mathrm{I}^{\mathrm{L}} \leq \mathrm{I}^{22} \leq \mathrm{I}^{3} \leq \cdots$ of the set $\left\{\mathrm{I}^{1} \mid \mathrm{L} \leq \mathrm{M}\right\}$

By the hypothesis, the set $\left\{\mathrm{I}^{\mathrm{L}} \mid \mathrm{L} \leq \mathrm{M}\right\}$ satisfies ACC , hence there is an integer $n$ such that $\mathrm{I}^{\mathrm{L}}=\mathrm{I}^{\mathrm{Ln}}$ for all $\mathrm{Z} \geq \mathrm{n}$. By Lemma 2.1, $\mathrm{L}_{n}=\mathrm{L}_{\mathrm{a}}$ for all $\mathrm{i} \geq \mathrm{n}$ Thus theorem has been proved

Theorem 2.6. Let M be an H -invariant module and the set $\left\{\mathrm{I}_{N} \mid \mathrm{N} \leq\right.$ M) satisfy the DCC. Then M satısfies ACC.

Proof. Let $\mathrm{N}_{1} \leq \mathrm{N}_{2} \leq \mathrm{N}_{3} \leq \cdots \cdots$ be any ascending chain of submodules of
M. Then we have a descending chain
$\mathrm{I}_{\mathrm{N} 1} \geq \mathrm{I}_{\mathrm{N} 2} \geq \mathrm{I}_{\mathrm{N} 3} \geq \cdots \cdots$ of the set $\left\{\mathrm{I}_{\mathrm{N}} \mid \mathrm{N} \leq \mathrm{M}\right\}$ which satisfies DCC by hypothesis and hence there is an integer n such that $\mathrm{I}_{\mathrm{N}_{1}}=\mathrm{I}_{\mathrm{Nn}}$ for all $\mathrm{i} \geq_{\mathrm{n}}$ By Lemma 2.2, $\mathrm{N}_{2}=\mathrm{N}_{\mathrm{n}}$ for all $\mathrm{i} \geq \mathrm{n}$.

Corollary 2.7. Let $M$ be an $H$-invariant module and the set $\left\{\mathrm{I}^{\mathrm{L}} \mid \mathrm{L} \leq\right.$ M) satiafy DCC. Then $M$ satisfies DCC.

Proof. It is proved by a similar argument of Theorem 2.5.

Corollary 2.8. Let $M$ be an $H$-invariant module and the set $\left\{\mathrm{I}_{\mathrm{N}}\right\} \mathrm{N} \leq$ M\} satisfy the ACC. Then $M$ satifies DCC.

Theorem 2.9. Let M be an H -invariant module and End(M) be left Notherian. Then M satisfies ACC.

Proof. Since $\operatorname{End}(M)$ is left Noetherian, the set $\left\{\mathrm{I}^{\mathrm{L}} \mid \mathrm{L} \leq \mathrm{M}\right\}$ satisfies ACC. By Theorem 2.5, M satisfies ACC.

Theorem 2.10. Let M be an H -invariant module and End(M) be right Noehterian. Then M satisfies DCC.

Proof. Since $\operatorname{End}(M)$ is a right Noetherian ring, the set $\left\{\mathrm{I}_{\mathrm{N}} \mid \mathrm{N} \leq \mathrm{M}\right\}$ satisfies ACC. Thence M satisfies DCC by Corollary 2.8 .

Corollary 2.11. Let M be an H -invariant module and $\mathrm{End}(\mathrm{M})$ be Noetherian. Then M satisfies ACC and DCC.

Theorem 2.12. Let $M$ be an $H$-invariant module and End(M) be left Artinian. Then M satifies DCC.

Proof. Since End(M) is left Artinian, the set $\left\{\mathrm{I}^{\mathrm{L}} \mid \mathrm{L} \leq M\right\}$ satisfies DCC. Then by Corollary 2.7 , M satisfies DCC.

Theorem 2.13. Let M be an H -invariant module and End(M) be right Artinian. Then $M$ satisfies ACC.

Proof. Since End(M) is right Artinian, the set $\left\{I_{N} \mid N \leq M\right\}$ satisfies DCC. Then by Theorem 2.6, M satisfies ACC.

Corollary 2.14. Let M be an H -invariant module and End(M) be Ar tımar. Then $\mathbf{M}$ satisfies ACC and DCC.

Proof. Form the above 2.12 and 2.13 , it follows immediateiy.
