pound. A possible mechanism for the formation of the azine is shown in Eq. (6)-(9).

$$
\begin{align*}
& \mathrm{PhC}(\mathrm{Me}) \mathrm{HN}=\mathrm{NH}(\mathrm{Me}) \mathrm{CPh}+\mathrm{Th}^{+} \quad \longrightarrow \\
& \mathrm{Th}+[\mathrm{PhC}(\mathrm{Me}) \mathrm{HN}=\mathrm{NH}(\mathrm{Me}) \mathrm{CPh}]^{+} \tag{6}
\end{align*}
$$

$$
\begin{align*}
& \mathrm{PhC}(\mathrm{Me}) \mathrm{H} \stackrel{+}{\mathrm{N}}-\dot{\mathrm{N}} \mathrm{H}(\mathrm{Me}) \mathrm{CPh} \longrightarrow \\
& \mathrm{PhC}(\mathrm{Me})=\mathrm{N}-\dot{\mathrm{N} H}(\mathrm{Me}) \mathrm{CPh}+\mathrm{H}^{+} \tag{7}
\end{align*}
$$

$$
\begin{align*}
\mathrm{PhC}(\mathrm{Me})=\mathrm{N}-\dot{\mathrm{N}} \mathrm{H}(\mathrm{Me}) \mathrm{CPh}+\mathrm{Th}^{+} \\
\mathrm{PhC}(\mathrm{Me})=\mathrm{N}-\stackrel{+}{\mathrm{N}} \mathrm{H}(\mathrm{Me}) \mathrm{CPh}+\mathrm{Th}  \tag{8}\\
\mathrm{PhC}(\mathrm{Me})=\mathrm{N}-\stackrel{+}{\mathrm{N}} \mathrm{H}(\mathrm{Me}) \mathrm{CPh} \longrightarrow \\
\mathrm{PhC}(\mathrm{Me})=\mathrm{N}-\mathrm{N}=(\mathrm{Me}) \mathrm{CPh}+\mathrm{H}^{+} \tag{9}
\end{align*}
$$

The formation of the thianthrene 5 -oxide (ThO) can be rationalized by hydrolysis of either some of $\mathrm{Th}^{+} \cdot$ by incompletely dried solvent during the course of reaction, or unused $\mathrm{Th}^{+}$during workup. ${ }^{10}$
No evidence for ethylbenzene was found from the $\alpha$-phenylethyl radical disproportionation reaction or from hydrogen abstraction from MeCN . When the reaction of $\mathrm{Th}^{+}$with meso-ABPE was carried out in the presence of $\mathrm{BrCCl}_{3}$ in MeCN , as we did earlier with AA, the formation of DBP was not stopped. Therefore, we can conclude that DPB is probably not formed in the oxidative reactions by dimerization of a-phenylethyl radical. Generally, radical is destined to abstract hydrogen atom fro MeCN rather than to dimerize in the absence of a competing reaction. ${ }^{11}$ The mechanism for the formation of DPB is rationalized in Scheme 2, which is very similar to that of formation of AdAd by $\mathrm{Th}^{+} \cdot{ }^{11} \mathrm{DPB}$ may have arisen from the DPB cation radical $[\mathrm{PhC}(\mathrm{Me}) \mathrm{HH}-$ ( Me ) $\mathrm{CPh}^{+\cdot}$ ], formed by a cage recombination between $\alpha$ phenylethyl cation and $\alpha$-phenylethyl radical, rather than the coupling between two a-phenylethyl radicals. Conversion of DPB cation radical into DPB would have to occur by elect-ron-transfer reaction from $\mathrm{Th}^{+}$within solvent cage. In that case, $\mathrm{Th}^{+}$. would have served as a catalyst for the formation of DPB from meso-ABPE. It is interesting to compare the yield of AdAd and DPB from oxidative decomposition of corresponding azoalkane $\mathrm{Th}^{+}$. Whereas $2.5 \%$ of AdAd was obtained from oxidation of AA $23.6 \%$ of DPB was formed in the oxidative of meso-ABPE by $\mathrm{Th}^{+}$. In the oxidation of mesoABPE with $\mathrm{Th}^{+\cdot}$, a-phenylethyl radical would not survive so long enough to be reduced to cation as tetriary adamantyl radical. Therefore, relatively lots of $\alpha$-phenylethyl radical would recombine with $\alpha$-phenylethyl cation to form a DPB without further oxidation in the solvent cage. Meso-ABPE gave $21.8 \%$ of meso and $1.8 \%$ of non-meso-DPB, indicating that some changes in orientations (by out-of-plane rotation) of the cations and radicals are occurring in these original cages prior to combination between $\alpha$-phenylethylcation and

$$
\mathrm{PhC}(\mathrm{Me}) \mathrm{HN}=\mathrm{NH}(\mathrm{Me}) \mathrm{CPh} \xrightarrow{\mathrm{Th}^{++}}\left[\mathrm{PhC}(\mathrm{Me}) \mathrm{HH}\left(\mathrm{Me}_{\mathrm{C}}\right) \mathrm{CPh}^{+\cdot} \mathrm{Th} \quad \mathrm{~N}_{2}\right]
$$

Scheme 2. Possible reaction pathways for the formation of 2,3diphenylbutane.
$\alpha$-phenylethyl radical.
In conclusion, the reaction of $\mathrm{Th}^{+}$, with meso-ABPE, possesing one $\alpha$ hydrogen, in acetonitrile follows not only the carbocationic route but also unundergoes tautomerization to its hydrazone, and no oxidative cycloaddition was observed.

Anisotropically refined atoms are given in the form of the isotropic equivalent displacement parameter defined as: $(4 / 3) \times[a 2 \times B$ $(1,1)+b 2 \times B(2,2)+c 2 \times B(3,3)+a b(\cos \gamma) \times B(1,2)+a c(\cos \beta)$ $\times B(1,3)+b c(\cos a) \times B(2,3)]$
graphite monochromated Mo-Ka radiation. The unit cell dimensions and an orientation matrix were obtained from a least-squares refinement of the setting angles of 25 reflections with $5.06<2 \theta<35.50^{\circ}$. The cell parameters and other crystallographic data are given in Table 1. The intensities of three standard reflections (002. 040,371) were measured after every one hour during the data collection. Intensities of these standard reflections remained constant within 0.007 \% per hour throughout the data collection. The data were corrected for Lorentz and polarisation effect. The 3418 reflections with $I>3.0 \sigma$ ( $I$ ) were used in the subsequent analysis. The structure was solved by Patterson methods and fourier maps using SHELXS ${ }^{6}$ and SDP $^{7}$ package programms on PC and PDP 11/23+ computers.
All the nonhydrogen atoms were found from a three dimensional fourier maps and refined anisotropically by fullmatrix least squares calculations on $F^{\prime}$ s. The funtion $\Sigma$ w ( $F_{0^{-}}$

$\left.F_{c}\right)^{2}$ was minimized with unit weights. The positional parameters of the hydrogen atoms were calculated with idealized bond length ( $1.0 \AA$ ). After one cyclic refinement of all atomic parameters with anisotropic temperature factors for all the nonhydrogen atoms and fixed isotropic ones for hydrogen atoms, the final results of structure solution are given in Table 1. The final atomic coordinates and the equivalent isotropic thermal parameters of the nonhydrogen atoms are listed in Table 2. The anisotropic thermal parameters of nonhydrogen atoms, the atomic coordinates and isotropic thermal parameters of hydrogen atoms, the least square planes and dihedral angles, the final values of observed and calcul-
ated structure factors are listed in Tables from S1 to S4. ${ }^{8}$
Magnetic Susceptibility Measurement. Static magnetic susceptibility data were collected in the temperature range $10-269 \mathrm{~K}$ on a powdered sample by using a MPMS-SQUID-magnetometer (Quantum Design Inc., USA). The sample weights and applied fields used were 9 mg and 5000 Gauss. The effective magnetic moments of 2.85 B.M. at 269 K are calculated by using the formula, $\mu_{e f}=2.83 \sqrt{x_{m} \cdot T}$ where $\chi_{m}$ is molar magnetic susceptibility per a molecule corrected for diamagnetism for all the constitutent atoms of 1,2 -ethylenediamine by the use of Pascal's constant. ${ }^{9}$ The electric conductance was not measured as the compound was expected

Flgure 1. Projection of packing arrangement with atomic numbering. The unit cell is oriented with +c axis horizontal, the $+a$ axis vertical and the $+b$ axis pointing toward the reader.

Figure 2. View of the $\mathrm{Ni}(\mathrm{en})_{3}{ }^{2+}$ cation. The configuration shown is $\Lambda(888)$, but in this centrosymmetric structure there are an equal number of $\Delta(\lambda \lambda \lambda)$ configurations. The last ring is the central ring ( $\mathrm{Ni}-\mathrm{N} 9-\mathrm{Cl} 3-\mathrm{C} 14-\mathrm{N} 10-\mathrm{Ni}$ ). The hydrogen atoms are not shown.
to be electric insulator.

## Results and Discussion

The unit cell consist of two crystallographically independent $\mathrm{Ni}(\mathrm{mnt})_{2}{ }^{2-}$ ions and a $\mathrm{Ni}(\mathrm{en})_{3}{ }^{2+}$ ion. The bond lengths and angles of the complex are listed in Table 3 and their corresponding e.s.d.'s are shown in parentheses. An ORTEP ${ }^{10}$ crystal packing diagram with atomic numbering scheme is shown in Figure 1. The central Ni -atoms of two $\mathrm{Ni}(\mathrm{mnt})_{2}{ }^{2-}$ are placed on the projection plane, but two Ni -atoms of $\mathrm{Ni}(e n){ }_{3}{ }^{2+}$ which are related by an inversion center, are deviated very slightly up and down from the plane. Although two averaged $\mathrm{Ni}-\mathrm{S}$ bond lengths ( 2.173 and $2.167 \AA$ ) are larger than those of $\mathrm{Ni}(\mathrm{mnt})_{2}{ }^{1-}$ anions, ${ }^{311}$ they are somewhat larger or smaller than those of $\mathrm{Ni}(m n t)^{2-}$ anions in other structures. ${ }^{3.12}$ The ring of the Ni-2 complex anion has larger deviations than that of the Ni-1 complex from the least square planes of $\mathrm{Ni}(\mathrm{mnt})_{2}{ }^{2-}$ ions which are assumed essentially planar. The dihedral angle between the two least square planes is $11.7^{\circ}$. The configuration of $\mathrm{Ni}(\mathrm{en})_{3}{ }^{2+}$ complex cation viewed down the pseudo threefold axis of the nickel ion is shown in Figure 2. The figure shows that the ethylenediamine chelate rings have identical conformations and three carbon-carbon bonds of ethylenediamine groups are almost parallel to the threefold axis. Therefore, the configuration of this cation may be described as $\Lambda(\delta \delta \delta)$; in this centrosym-

Figure 3. Temperature dependence of the gram magnetic susceptibility $\chi_{8}$ ang the inverse susceptibility.
metric space group there are also equal number of the cation with enantiomeric $\Delta(\lambda \lambda \lambda)$ form. All of the known configurations of $\left[\mathrm{Ni}(\mathrm{en})_{3}\right]^{2+}$ cations, ${ }^{13}$ which form salts with sulfate and nitrate ions, but not involving any water molecules, have been reported to be $\Lambda(\delta \delta \delta)$ as in this complex.

Corey and Bailar ${ }^{14}$ calculated that the most stable configuration for $\left[M(e n)_{3}\right]^{n+}$ ion is $\Lambda(8 \delta \delta)$. However, the configurations of $\left[\mathrm{Cr}(\mathrm{en})_{3}\right]^{3+}$ anions ${ }^{15}$ were reported as $\Lambda(\delta \lambda \lambda), \Lambda(\delta \delta \lambda)$ and $\Lambda(\lambda \lambda \lambda)$, but these complexes have one and half more hydrate water molecules. Raymond et al.$^{152}$ proposed that the higher energy conformers are stabilized by hydrogen bonds. They found the $\Lambda(\delta \delta \lambda)$ conformer involved in three strong hydrogen bonds, the $\Lambda(\delta \lambda \lambda)$ conformer in seven and the $\Lambda$ $(\lambda \lambda \lambda)$ conformer in ten hydrogen bonds.

In order to confirm the above proposed configuration of $\mathrm{Ni}(e n)_{3}{ }^{2+}$ cation of the title complex, the following factors were compared and calculated with each other in details. The bond distances and angles of the third conformation (N9-C13 1.47, C13-C14 $1.48 \AA$, N9-C13-C14 108.9, C13-C14$\mathrm{N} 10 \mathrm{109.1} 1^{\circ}$ ) of $\mathrm{Ni}(e n)_{3}{ }^{2+}$ configuration were essentially deviated larger than the corresponding averaged values ( 1,407 , $1,434 \AA, 113.5,113.9^{\circ}$ ) of two other comformations. So then, we calculate the dihedral angle $\alpha$ between the plane which contains the ring carbon atoms and the metal atom and the plane which contains the ring nitrogen atoms and the metal atom and also the angles $\beta$ between the two nitrogen atoms as one looks down the carbon-carbon bond.

The angles $\alpha$ and $\beta$ of three conformations were responded to 21 and 43.6 for A, 20 and 42.4 for B, 27.3 and $53.9^{\circ}$ for $C$ ring respectively. On the other hand, two or four weak hydrogen bonds between nitrogen atoms of cations and nitrogen atoms of neighboring anions are possible, when NN bond lengths of hydrogen bonds are assumed to be less than $3.4 \AA$. The distances between two nitrogen atoms of first two conformations of complex cation and two nitrogen atoms of two complex anions are closer than those of the last conformation. Even through it may be proposed as $\Lambda(\delta \delta \lambda)$ instead of $\Lambda(\delta \delta \delta)$, based on the above discussions for the configuration of $\mathrm{Ni}(\mathrm{en})_{3}{ }^{2+}$ ion, it should be described as $\Lambda$ ( 88 ) on account of the positive values of the all angles of $\alpha$ and $\beta$.

The gram magnetic susceptibility of a powdered samples is plotted as a function of temperature in Figure 3. The in-
verse magnetic susceptibility is fitted excellently to a straight line in the temperature range $10-269 \mathrm{~K}$. The susceptibility exhibts typical Curie law depedence, with the Curie constant of $1.014 \mathrm{emu} \mathrm{K} \mathrm{mol}{ }^{-\mathrm{t}}$.

# Valence States of $\mathbf{S H}^{\mathbf{2 +}}$ by Ab Initio Effective Valence Shell Hamiltonian 

Jong Keun Park and Hosung Sun*

Received June 19, 1992

Recently the electronic states of doubly positive diatomic cations have been investigated extensively ${ }^{1,2}$. In those studies a few quasibound states of doubly positive diatomic cations have been found. There is a repulsive force between two singly positive monatomic cations. The repulsive force is overcome sometimes by redistribution of electron densities when a doubly positive diatomic cation is formed. Therefore metastable bound states can exist in some cases. In other words the avoided curve crossing between a state arising from an ion-ion asymptote (dissociation limit) and a state with the same symmetry arising from an ion-neutral asymptote is a main reason for the existence of quasibound states in doubly positive diatomic cations.

We have studied the nature of the effective valence shell Hamiltonian ( $F^{\prime \prime}$ ) which is based on the quasidegenerate many-body perturbation theory ${ }^{3}$. One of remarkable features of $H^{*}$ is that the effective $H^{\prime}$ operator can reproduce all the valence states of a neutral molecule and its ions simultaneously regardless of its charge states. Once the matrix elements of $H^{p}$ are evaluated for a neutral molecule, the same matrix elements can be used to determine the valence states of its singly positive, doubly positive, $\cdots$ cations.
The existence of the bound states in $\mathrm{NO}^{2+}, \mathrm{O}_{2}^{2+}$, etc. may be easily predicted. But for the first row diatomic monohydrides, say, $\mathrm{CH}^{2+}$, or $\mathrm{NH}^{2+}$ cation, the existence of unusually stable states may not be easily understood. If two electrons are removed from the $1 \pi^{2}$ orbital of neutral $\mathrm{NH}, \mathrm{NH}^{2+}$ may exist because the $1 \pi$ orbital of neutral NH has basically nonbonding character. For $\mathrm{CH}^{2+}$, the prediction of its existence is not so simple because at least one electron should be removed from a bonding 30 orbital of neutral CH to form $\mathrm{CH}^{2+}$ cation. We have previously studied the $\mathrm{CH}^{2+}$ cation and found no bound states. ${ }^{4}$ Therefore so far the $H^{y}$ has been mainly applied to neutral molecules and singly positive cations. But recently doubly positive cations of various second row diatomic monohydrides have been studied by configuration interaction (CI) method ${ }^{5,6}$. We are encouraged by these studies so that now we apply the $H^{v}$ method to these systems.

In the present work, we have performed $H^{\prime}$ calculations on the $\mathrm{SH}^{2+}$ cation. The $\mathrm{SH}^{2+}$ cation has been studied previously ${ }^{2,6}$. But one should note that a single $H^{p}$ calculation simultaneously produces all the valence state energies with same accuracy. So that our present $H^{*}$ calculations reveal a composite picture of the $\mathrm{SH}^{2+}$ potential energy curves of all the valence states.

The second order effective valence shell Hamiltonian calcalculations for $\mathrm{SH}^{2+}$ are performed with a contracted Gaussian basis set of $[7 s 5 p 3 d]$ for sulfur and $[2 s 1 p]$ for hydrogen?. Molecular orbitals are obtained from the SCF (self-consistent-
