# The Crystal and Molecular Structure of Sodium Magnesium Tris(oxalato)Chromate(III) Decahydrate, $\mathbf{N a M g}\left[\mathrm{Cr}(\mathrm{Ox})_{3}\right] \cdot \mathbf{1 0 H}_{\mathbf{2}} \mathrm{O}$ 

Jung-Sun Suh, Jung-Yup Shin, Cheonho Yoon, Kyu-Wang Lee<br>Il-Hwan Suh*, Jin-Ho Lee*, Bo-Young Ryu*, and Sung-Su Lim*<br>Department of Chemistry, Myongii University Yongin, Kyonggi-do 449-728<br>*Department of Physics, Chungnam National University, Taejon 305-764

Received November 2, 1993
$\mathrm{NaMg}\left[\mathrm{Cr}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{3}\right] \cdot 10 \mathrm{H}_{2} \mathrm{O}$ crystallizes in the trigonal space group $\mathrm{P} \overline{3} \mathrm{c} 1$, with $a=b=16.969(3), c=12.521(3) \AA, \alpha=\beta=90^{\circ}$, $\gamma=120^{\circ}, \rho=1.734 \mathrm{gcm}^{-3}, \mu=6.46 \mathrm{~cm}^{-1}, Z=6$. Intensities for 1062 unique reflections were measured on a four-circle diffractometer with Mo $K \alpha$ radiation $(\lambda=0.71069 \AA$ ). The structure was solved by direct methods and refined to a final $\omega$ R value of 0.084 . X-ray crystal structure showed that magnesium ion appears to be occupied over two sites with the occupancy ratio of $2: 1$. The crystal possesses 10 water molecules instead of previously estimated 9 water molecules.

## Introduction

Even though the magnetic and electronic properties of [ Cr $\left.(o x)_{3}\right]^{3-}\left[o x=\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)^{2-}\right]$ have been extensively studied under the guidelines of conventional ligand field theory, the results are not always in agreement. ${ }^{1-3}$ The type of space group has been controversially discussed for the interpretation of EPR and PMR results. ${ }^{4}$ Band assignments in the sharp lines
arising from $t_{2_{8}}{ }^{3}$ intraconfigurational transition are still controversial.

Mortensen reported $20 \mathrm{~cm}^{-1}$ splitting of ${ }^{2} E_{g}$ tine in NaMg salt. ${ }^{2}$ while Coleman observed large variance of ${ }^{2} E_{g}$ splittings (from 2 to $115 \mathrm{~cm}^{-1}$ ) which have been attributed to the degree of hydration and the effects of the counter ion in a molecule. ${ }^{5}$ Recently Schönherr et al. assigned the ${ }^{2} E_{g}$ lines split by $2.3 \mathrm{~cm}^{-1}$ which was rationalized by the angular over-
lap model calculation on the basis of $D_{3}$ symmetry with variation of angular geometry. ${ }^{6}$ Hoggard suggested that the anisotropic $\pi$-bonding could alter the sharp line position significantly and may result in a very large ${ }^{2} E_{k}$ splittings. ${ }^{7}$
Since the splittings of sharp lines are very sensitive to the metal-ligand geometry, the knowledge of crystal and molecular structure is essential for the detailed analyses of electronic and magentic properties. The available structural data of this comple: up to now, however, are very limited. We give here the result of an accurate three-dimensional single crystal X-ray analysis of the structure of $\mathrm{NaMg}\left[\mathrm{Cr}(\mathbf{o x})_{3}\right] \cdot 10$ $\mathrm{H}_{2} \mathrm{O}$

## Experimental

Sodium tris(oxalato)chromate(III), $\mathrm{Na}_{3}\left[\mathrm{Cr}(\mathrm{OX})_{3}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ was prepared by standard method. ${ }^{8}$ Twice crystallized $\mathrm{Na}_{3}\left[\mathrm{Cr}(\mathrm{ox})_{3}\right]$ $\cdot 3 \mathrm{H}_{2} \mathrm{O}(4.39 \mathrm{~g})$ and $\mathrm{MgCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ ( 2.03 g ) were dissolved in water and recrystallized by slow evaporation in the dark. Dark blue hexagonal crystals were obtained. ${ }^{9}$
The Laue group of the crystal was confirmed by X-ray photography. ${ }^{10}$ A crystal of approximate dimensions of $0.4 \times$ $0.5 \times 0.3 \mathrm{~mm}$ was mounted and aligned on an Enraf-Nonius CAD-4 diffractometer. The accurate cell parameters were refined from setting angles of 25 reflections with $11.521^{\circ}<\theta<$ $13.975^{\circ}$. The systematic absences of $h k l: l=2 n$ and $00: l=$ $2 n$ showed two possible space groups $\overline{\mathrm{B}} \mathrm{c} 1$ and P3cl. The space group, $\mathrm{P} \overline{3} \mathrm{cl}$, was confirmed after the elucidation of the crystal structure. The 1062 independent reflections in the range of $0 \leq h \leq 16,0 \leq k \leq 16,0 \leq l \leq 14$ for an asymmetric unit ${ }^{11}$ were collected using graphite-monochromated Mo Ka radiation and $\omega / 2 \theta$ scan mode, $\omega$-scan angle $=(0.65+0.34$ $\tan \theta)^{\circ}, \theta_{\text {mux }}=24^{\circ}$. All data were converted to $E_{n}$ values following correction for L-P factors. The four heavy atoms were located by using direct method (SHELX86) ${ }^{12}$ and all non-hydrogen atoms were found on subsequent difference Fourier maps. The structure was refined by full-matrix least squares with SHELX76 ${ }^{13}$ and function minimized was $\Sigma \omega\left(\left|F_{o}\right|-\left|F_{c}\right|\right)^{2}$ with unit weights.
The positions of $\mathrm{Cr}, \mathrm{Na}, \mathrm{Mg}$ and $\mathrm{Mg}^{*}$ atoms were assigned according to their electronic densities and later on they were confirmed by interatomic bond lengths and angles. As the heavy atoms $\mathrm{Cr}, \mathrm{Na}, \mathrm{Mg}$ and $\mathrm{Mg}{ }^{*}$ are on the special positions, they were refined with fixed occupancy factors of $1 / 2$, $1 / 2,1 / 6$ and $1 / 3$ respectively and with $u_{2 z}=2 u_{12}, 2 u_{23}=u_{13}$ for Cr and $\mathrm{Na}, u_{11}=u_{22}=2 u_{12}, u_{13}=u_{23}$ for Mg and $\mathrm{Mg}{ }^{*}$ atoms. ${ }^{14}$ Number of parameters refined was 138. A final difference Fourier synthesis showed a number of small peaks in the vicinity of the heavy atoms. Final reliability factors were $R=0.084$ with average $\Delta / \sigma=0.0026 \Delta \rho_{\text {max }} / \Delta \rho_{\text {min }}=0.69$ $1-0.96 \mathrm{e} \AA^{3}$ in the final $\Delta \rho$ map, and $S=4.56$. Final positional parameters, occupancy factor and $U_{\text {eq }}$ for non-hydrogen atoms are given in Table 1. All computations were carried out using the MICROVAX/ 3400 computer.

## Results and Discussion

As shown in Table $1, \mathrm{Cr}$ and Na atoms occupy special positions with 2 -fold symmetry with their occupancy factors of $1 / 2$. The magnesium ion occupies over two sites in such a way that one third of Mg is located at $(0,0,1 / 4)$ with

Table 2. The catculation of the number of atoms in a molecule

| Atom | Occupancy <br> factor | No. of <br> symmetry | No. of <br> atom |
| :---: | :---: | :---: | :---: |
| Cr | $1 / 2$ | 2 | 1 |
| $\mathrm{Mg}(1)$ | $1 / 6$ | 2 | $1 / 3$ |
| $\mathrm{Mg}(2)$ | $1 / 3$ | 2 | $2 / 3$ |
| Na | $1 / 2$ | 2 | 1 |
| $\mathrm{O}(6$ atoms $)$ | 1 | 2 | 12 |
| $\mathrm{C}(3$ atoms $)$ | 1 | 2 | 6 |
| $\mathrm{O}(5$ water molecules $)$ | 1 | 2 | 10 |

2 -fold and 3 -fold symmetries, and two-third of $\mathrm{it}, \mathrm{Mg}^{*}$, is located at ( $2 / 3,1 / 3,0.2573$ ) with a 3 -fold symmetry. Therefore the occupancy factors of Mg and $\mathrm{Mg}^{*}$ atoms are $1 / 6$ and $1 / 3$, respectively. Since in a molecule itself there is a 2 -fold symmetry along (110) at the site of $z=1 / 4$, the half molecule of this compond is in the asymmetric unit and the chemical formula of the molecule is $\mathrm{NaMg}\left[\mathrm{Cr}_{\left.\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{3}\right] \cdot 10 \mathrm{H}_{2} \mathrm{O}}\right.$ as shown in Table 2.

The main bond lengths and angles in $\mathrm{Cr}(\mathrm{ox})_{3}{ }^{3-}$ unit and the environments of $\mathrm{Na}^{+}, \mathrm{Mg}^{2-}$ ions and water molecules are characterized by their nearest neighbor contacts in Table 3 and 4. The perspective drawing of $\mathrm{Cr}(\mathrm{ox})_{3}{ }^{3-}$ anion with atomic numbering scheme and the crystal packing of NaMg $\left[\mathrm{Cr}(\mathrm{ox})_{3}\right] \cdot 10 \mathrm{H}_{2} \mathrm{O}$ are shown in Figure 1 and 2 respectively.

The X -ray structural analysis reveals the composition of the complex as decahydrate, $\mathrm{NaMg}\left[\mathrm{Cr}(\mathrm{ox})_{3}\right] \cdot 10 \mathrm{H}_{2} \mathrm{O}$. This, has been reported as nonahydrate without the inclusion of analytical data, but presumably by elemental analysis. ${ }^{1289}$ The similarity in elemental percentage between nona and decahydrate could have led to nonahydrate formula.

The structure of $\mathrm{Cr}(\mathrm{ox})_{3}{ }^{3-}$ anion in the complex is very similar to that of $\mathrm{K}_{3}\left[\mathrm{Cr}(\mathrm{Ox})_{3}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$, structure determined by Talyor. ${ }^{15}$ The average bond length of $\mathrm{Cr}-\mathrm{O}$ is $1.977 \AA$. The octahedron around the Cr atom is distorted by up to $16.0^{\circ}$ from the ideal value of 90 and $180^{\circ}$, and the oxalate ligands are nearly planar within $0.1291(10) \AA$ deviation from the plane. In oxalate ligands, inner C-O bonds (Avg. 1.288 $\AA$ ), where the oxygen is coordinated to the $\mathrm{Cr}^{3+}$ ion are longer than the outer C-O bonds (Avg. $1.216 \AA$ ) which may represent the double bond character of outer C-O bond. The average bond length of C-C is $1.588 \AA$.

The crystallographic environments of $\mathrm{Na}^{+}$and $\mathrm{Mg}^{2+}$ ions
are very peculiar. $\mathrm{Na}^{+}$ion is attached to oxygen atoms of oxalate anion while $\mathrm{Mg}^{2+}$ ion is surrounded by oxygen atoms of water molecules, presumably through the electrostatic attraction. $\mathrm{Na}^{+}$ions are attached to outer oxalate oxygen atoms ( $04,05,06$ and three other oxygens generated by 2 -fold symmetry) and three oxalate groups are surrounding $\mathrm{Cr}^{3+}, \mathrm{Na}^{+}$ ions alternatively with the same $z$-coordinate by $1 / 4$, so these form an infinite layer parallel to (001) plane with interlayer distance of $6.26 \AA$ (Figure 2). The $\mathrm{Na}-\mathrm{O}$ distances range from 2.371 to $2.415 \AA$ with mean value of $2.388 \AA$. This agrees well with sum of effective ionic radii of $\mathrm{Na}^{+}(1.16 \AA)$ and $\mathrm{O}^{2-}(1.21 \AA)$ and with the $\mathrm{Na}-\mathrm{O}$ distance of sodium D-tartrate

Figure 1. Molecular structure and atomic labelling scheme. The asymmetric unit corresponds to one-half of the molecule, the other half being generated by the crystallographic two fold axis.

Figure 2. A diagram of a unit-cell packing for the molecule: origin, lower left; a-axis, horizontal; b-axis, vertical.
dihydrate. ${ }^{16}$
Two different $\mathrm{Mg}^{2+}$ sites in this complex are manifested from difference Fourier map. Oxygen atoms of crystalline water around the Mg and $\mathrm{Mg}^{*}$ atoms form the different geometry in such a way that Mg interact with $\mathrm{O}(7)$ and symmetryrelated five other $\mathrm{O}(7)$ atoms and $\mathrm{Mg}^{*}$ interact with $\mathrm{O}(9), \mathrm{O}(10)$ and the symmetry-related four other themselves. This produces octahedral environment for the $\mathrm{Mg}^{2+}$ ions (Figure 3 and 4). The $\mathrm{Mg}-\mathrm{O}$ distances vary from 2.053 to $2.101 \AA$ with mean vlue of $2.068 \AA$ as summarized in Table 3 and 4. This is in good agreement with $2.074 \AA$ found in $\left[\mathrm{Mg}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ ion. ${ }^{17}$ The other oxygens from crystalline waters ( $O(8), O(9)$ ) are located in between Mg and $\mathrm{Mg}^{*}$ ions, and they are associated with other oxygen atoms of oxalate anions and of water molecules, probably through hydrogen bonding. Though the definite proot for hydrogen bonding is lacking since the hydrogen atoms of the water molecules could not be located, one may take the evidence of hydrogen bonding if $\mathbf{O - O}$ dista-

Figure 3. A stereoview of the environment of Mg atom.

Figure 4. A stereoview of the environment of $\mathrm{Mg}^{*}$ atom.
nce less than $3 \AA$ which is sum of the van der Waals radius of oxygen. These hydrogen bonds formed through water molecules interconnect the two parallel layers of sodium tris (oxalato) chromate unit separated by $c / 2$ and may stabilize the molecular packing.

These two $\mathrm{Mg}^{2+}$ ions will create two different ligand field enviroment for the $\mathrm{Cr}(\mathrm{ox})_{3}{ }^{3-}$ and may cause the small (2$3 \mathrm{~cm}^{-1}$ ) splitting in optical spectrum. One may suggest the possibility of this splitting as zero field splitting. However, EPR study suggested the magnitude of zero field splitting as $0.9 \mathrm{~cm}^{-1}$. Mortensen suggested that this optical splitting is due to exchange interaction between separate $\operatorname{Cr}(o x)_{3}{ }^{3-}$ ions. ${ }^{2}$ But it is very unlikely since the closest $\mathrm{Cr}-\mathrm{Cr}$ separation is determined as $8.282 \AA$ and the same splitting is observed in 1-5\% $\mathrm{Cr}(\mathrm{ox})_{3}{ }^{3-}$ doped in NaMg salt of $\mathrm{Al}(\mathrm{ox})_{3}{ }^{3-}$ complex where the separation of $\mathrm{Cr}-\mathrm{Cr}$ is even expected to be larger.

# Time-resolved UV Fluorescence Spectroscopy of Aorta and its Related Chromophores, Collagen and Elastin, Using 320 nm Excitation 

Young D. Park<br>Department of Chemistry Ajou University, Suwon 441-749<br>Received December 24, 1993

#### Abstract

Fluorescence time decay of human aorta has been measured at $380,440,480 \mathrm{~nm}$ using 320 nm excitation and timecorrelated single photon counting technique. Fluorescence decay was found to be nonexponential at all emission frequencies. The normal and diseased sample showed significantly different fluorescence behaviors at 380 nm while this time decay difference was decreased in the fluorescence at 440 and 480 nms . The decay data were multiexponential and were analyzed with two exponential decay constants. The fluorescence decays were compared with and analyzed in terms of collagen and elastin.

## Introduction

Laser-induced fluorescence (LIF) spectroscopy has proved to be one of the most sensitive detection methods and has become a powerful tool in the field of analytical chemistry. LIF spectroscopy has been widely used in biology and medicine and more recently in the characterization of human tissue. ${ }^{1-4}$ The study of arterial wall spectroscopy, in particular, has drawn considerable interest because atherosclerosis account for a large proportion of heart attacks and cases of ischemic heart disease ${ }^{5}$. Atherosclerosis also accounts for many strokes, numerous instances of peripheral disease, most aneurysms of the lower abdminal aorta, which can rup-
ture and cause sudden fatal hemorrhage ${ }^{6}$. Laser induced fluorescence has great potential for arterial wall diagnosis due to its sensitivety, and its ability to be monitored remotely using optical fiber probe. Since fluorescence emission is affected by the fluorophors constitution and their surrounding environments, normal and diseased plaque tissue are expected to yield different fluorescence behavior both in frequency and time domain. In this paper, we would like to focus our discussion on the time resolved study of aorta fluorescence spectroscopy.

Aorta is a large elastic artery and is made of three major microscopic layers: the intima, the media, and the adventitia ${ }^{6}$. These layers are separated by elastic sheets. The intima is
