---

**Abstract:** An extraction chromatographic method of separating rare earth impurities from high purity  $\text{Nd}_2\text{O}_3$ ,  $\text{Sm}_2\text{O}_3$ ,  $\text{Gd}_2\text{O}_3$ ,  $\text{Er}_2\text{O}_3$ ,  $\text{Dy}_2\text{O}_3$  and  $\text{Yb}_2\text{O}_3$  was studied by using  $\text{HCl-NH}_4\text{Cl}$  as moving phase and P507 as stationary phase. After the impurities were enriched from the eluate by chelant-activated carbon, the active carbon was ashed and the ignited residue was used to prepare the sample electrode for spark source mass spectrometric determination. The impurities in 99.9999% rare earth oxide can be determined by the proposed method with recovery over 80%.

**Keywords:** Extraction chromatography, Rare earth element, Spark source mass spectrometry

---

### 1. Introduction

There still exist definite difficulties in analysing the rare earth (RE) impurities in 99.9999% multi-isotopic RE oxide (Nd, Sm, Gd, Er, Dy and Yb) directly with spark source mass spectrometry (SSMS), because the matrix seriously interferes the determination of the adjacent elements. In order to eliminate the matrix interference and improve the analytical sensitivity, it is necessary to carry out chemical separation. With mono (2-ethylhexyl) 2-ethylhexyl phosphonate (P507) containing resin as the stationary phase and  $\text{HCl-NH}_4\text{Cl}$  as the moving phase, the impurities can be separated in group or individually from the matrix after selecting appropriate separation conditions<sup>[1-3]</sup>. The

matrix eluate is discarded and the impurities eluate is collected and absorbed on the chelant-active carbon column. With this method, the impurities can be concentrated up to 20 times and the sensitivity is greatly improved.

### 2. Experimental

#### 2.1 Apparatus and Reagents

Superthermostat: Type CS-501, Chungking Experimental Equipment Works (China)

Spark source mass spectrometer: Type MS-702, Associated Electrical Industries LTD (England)

Scanning microphotometer: Type G II (Germany)

Extraction chromatographic column:  $\Phi 16 \times 1000$  mm, with thermostatic pipe

Chelant-active carbon column:  $\Phi 8 \times 100$  mm

P507 resin; containing 55% P507, Shanghai Yue-long Nonferrous Metal Limited Company (China)

Active carbon; A. R., Beijing Guanghua Timber Mill (China)

Hydrochloric acid, Ammonium chloride, Sulfosalicylic acid and Hexamethylenetetraamine; A. R.

RE impurity standardized solution: 1 mg/mL

RE matrix standardized solution: 250 mg/mL

## 2.2 Preparation of chromatographic column

The column was packed with paste method. Clog some glass silk at the end of the column and stir the P507 resin evenly to gruel state and then pour the resin into the column about 900 mm. Stir the resin in the column with long glass rod in order to remove the bubble. With the resin sedimentating, new resin is added continuously into the column. When the column bed height is about 800 mm, the surplus resin is taken out from the column and the top of the bed is clogged tightly with some glass silk. The column is eluted with 1:1 HCl until there isn't  $\text{Fe}^{3+}$  in the eluate (detected with  $\text{NH}_4\text{SCN}$ ) and then eluted with distilled water to neutrality. Then the column can be used.

## 2.3 Procedure of the separation of the resin column and Detection of rare earth elements

Adjust the mixed solution of RE matrix and adjacent elements to PH 2~4 and inject the solution into the column, controlling the column temperature about  $50 \pm 5^\circ\text{C}$  and the sample injection rate at  $0.2 \text{ mL} \cdot \text{min}^{-1} \cdot \text{cm}^{-2}$ . When the mixed solution is on the same level with the column bed, rinse the beaker and the column wall with a little distilled water several times. After the rinsing solution is on the same level with the column bed, shut the clip and let the column balance about 5~10 hours.

Link the separating funnel filled definite acidity

eluent with the column and control the elution flow rate at  $1 \text{ mL} \cdot \text{min}^{-1} \cdot \text{cm}^{-2}$ . The eluate is collected every 25 mL. Taking 15 mL out of the every 25 mL eluate, add 3~5 mL 10% sulfosalicylic acid (masking the interference elements, such as Fe, Al ect.) and 2~3 drops 0.5% xylenol orange indicator into the solution, then adjust the solution to red with 1:1  $\text{NH}_3 \cdot \text{H}_2\text{O}$  and then to yellow with 1:1 HCl and add two drops more 1:1 HCl. In the end, add 3 mL 10% hexamethylenetetraamine buffer and titrate the solution to brilliant yellow with 0.002 mol/L EDTA.

## 2.4 Concentration and Determination

The impurities eluate are mixed and adjusted to pH 7~8 and the internal standard element is added to it. And then, the trace RE impurities are absorbed on active carbon by passing through the chelant-active carbon column<sup>[4]</sup>. The active carbon with impurities is ashed and the ignited residue is ground evenly and pressed into "T" type electrode and determined in optimum SSMS parameters.

## 3. Results and Discussion

### 3.1 Chemical separation

The optimum separation acidity and matrix load capacity are selected by experiment. With those optimum conditions, each rare earth impurity is completely separated and the recovery is 90~110%.

#### 3.1.1 Selection of elution acidity

The elution acidity influences the separation effect directly. With 200 mg RE oxide as matrix, adding respectively 1 mg other 14 rare earth elements (REE) as impurities, we have separated the REE with different acidity eluents and selected the optimum separation acidity. The result is shown in Table I and elution curves are shown in Figure 1~7. Table II~VII show the recovery and the blank area of each REE.

Table I Elution Acidity of Each REE in Different Matrix (HCl, mol/L+1 mol/L NH<sub>4</sub>Cl)

### 3.1.2 Influence of matrix load capacity

The matrix load capacity (MLC) is an important factor of effecting the chromatographic efficiency. If the MLC is changed, the recovery and the elution volume will be

changed in the meantime, which are shown in Table VIII. From the Table, we can see that the REE will be separated completely if the MLC is below 250 mg.

Table VIII Influence of Matrix Load Capacity

| load capacity<br>(Gd, mg) | Eu          |                    | Tb          |                    |
|---------------------------|-------------|--------------------|-------------|--------------------|
|                           | recovery(%) | elution volume(mL) | recovery(%) | elution volume(mL) |
| 20                        | 112         | 650                | 117         | 1090               |

| 250                       | 100         | 1200               | 99          | 1000               |

### 3.2 Sample analysis

In the course of analysing a sample with SSMS, because the vacuum spark discharge in ion source comprises many complicated physical processes in producing ion current and the ionization efficiency of different element and the instrument transmission efficiency of different ion are not alike completely and the mass response of the photoplate is also different, the sensitivity of every element is inconsistent. The relative sensitivity factor is evaluated to correct the semiquantitative

result by using the synthetic standard sample of similar substance. And then, the quantitative analytical result can be acquired.

We have analysed the trace RE impurities in 99.9999% RE oxide with the relative sensitivity factor method. The relative sensitivity factor and the relative standard deviation are listed in Table IX and the accuracy is shown in Table X. Table XI shows the analytical result of the samples.

Table IX Relative Sensitivity Factor (R) and Relative Standard Deviation (RSD%)

| element | La  | Ce  | Pr  | Nd  | Sm  | Eu   | Gd   | Tb  | Dy  | Ho  | Er  | Tm   | Yb  | Lu  |

### Conclusions

This method which can eliminate the matrix interference satisfactorily solves the problem of reconcentrating ultra trace RE impurities in big volume eluate. The enrichment multiple is  $10^3$  and the recovery is up to 99%. Furthermore, comparing with extraction enrichment method, this method has the advantage of no pre-concentration, simplicity and little contamination.
