#### Abstract

Acid-catalyzed porphyrin formation from meso-aryltripyrromethanes and 2,5-bis( $\alpha$-hydroxy- $\alpha$-phenyl)methylfuran is studied. The condensation resulted in selective scrambling of tripyrtomethanes when the condensation was carried out with catalytic amounts of $\mathrm{BF}_{3}$ in methylene chloride. But the reaction carried out with $p$ TsOH or $\mathrm{BEl}_{3}$ catalysts in the presence of $\mathrm{NH}_{4} \mathrm{Cl}$ in acctonitrile, single porphyrin product was isolated without scrambling of starting tripyrromethane. The yields of porphyrin in these studies were somewhat lower than those of 2-2 condensations or aldehyde-pyrrole condensations.

## Introduction

We have been interested in synthesizing porphyrin building blocks for various model systems such as porphyrinbased molecular wire and molecular devices. The synthesis of meso-substituted porphyrins has traditionally been achieved by Rothemund method ${ }^{\prime}$ or Adler method. ${ }^{-4}$ More recently, the new method has been developed by Lindsey. ${ }^{5-7}$ The yields of porphyrins also have been significantly improved by applying various catalysts. Direct synthesis of porphyrins bearing different substituents at meso positions was only possible by Macdonalds type $2+2$ condensation of two different dipyrromethanes. A trans-substituted porphyrins can be synthesized from mixed aldehydes condensations, but the separation of the desired isomers is usually difficult. The $3+1$ approach on the other hand can be applied in the regioselective synthesis of cis-substituted porphyrins or $R_{1} R_{2}\left(R_{3}\right)_{2}$ type porphyrins as shown in Scheme 1 . Regardless the position of linking (meso) carbon, it may be possible to synthsize the desired porphyrin as single isomer.

In order to broaden the scope and limitation of the synthesis of the model compounds, we have investigated several reaction parameters on the yields of porphyrins obtained in $3+1$ condensation. The parameters studied include acid catalysts, acid concentration, reactant concentrations, the added inorganic salts and reaction times. These studies revealed that the $3+1$ condensation generally gave lower yields of porphyrin compared to other methods. ${ }^{8.9}$

## Experimenral Section

${ }^{1}$ H NMR spectra ( 400 MHz , Bruker DPX-400, IFS48), IR spectra (JASCO IR100) and absorption spectra (Kontron 941) were collected routinely. Mass spectra were obtained by FAB. The formed porphyrins from crude reaction mixture

Scheme 1
were analyzed by laser desorption ionization mass spectrometry (LD-MS, Bruker Proflex II) without matrix. The progress of porphyrin forming reactions was monitored spectroscopically and extent of scrambling in the crude reaction mixture determined using LD-MS. The crude oxidized spectroscopic aliquats were spotted directly onto a LD-MS target with prior filtration through a pad of silica in a Pasteur pipette. The quantitative absorption spectral measurements were performed using Kontron 941 spectrometer. Pyrrole was distilled under low pressure and used prior to colorization. Acetonitrile used as reaction solvent as received (Aldrich). $\mathrm{BF}_{3}$-etherate (Aldrich, redistilled grade), $p$-toluenesulfonic acid ( $p-\mathrm{TsOH}$ ), DDQ (aldrich) and TFA (Aldrich) were used as received. Column chromatography was routinely done using silica gel (Merck, 230-400 mesh). Compound 4 was obtained by reducing corresponding ketone. ${ }^{8}$ Diols ( $\mathbf{6 a}, \mathbf{6} \mathbf{b}$ ) were synthesized as reported previously. ${ }^{10}$ The $3+1$ condensations were performed in small scale, with spectroscopic yield determination. The usual procedures are following; the diol ( 0.1 mmol ) was dissolved in acetonitrile $(10 \mathrm{~mL})$ and tripyrromethane $(0.1 \mathrm{mmol})$ was added. Then $\mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}(2 \mathrm{mM})$ was added to the stirred solution. The reaction was monitored at various time (min) by removing $50 \mu \mathrm{~L}$ of aliquats from the reaction mixture. The aliquat were added to $300 \mu \mathrm{~L}$ of 0.0 I M solution of DDQ in toluene to oxidize any porphyrinogen formed. $25 \mu \mathrm{~L}$ of the aliquat of this solution was diluted again with appropriate amount of $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{EtOH}(3 / 1)$ to the total volume of 3.0 mL . The band at 416 nm was characteristic of a Soret band of $\mathrm{N}_{3} \mathrm{O}$-porphyrin. The spectroscopic yields then were determined assuming molar absorptivity of 160,000 . The minimum change of the absorbance was taken in order to determine the relative yields of porphyrin in different time.

5 -(p-lodophenyl)-10-phenyltripyrromethane (5). $\mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}(0.28 \mathrm{~g}, 1.98 \mathrm{mmol})$ was added dropwise to the stirring mixture of $4(0.90 \mathrm{~g}, 1.98 \mathrm{mmol})$ and pyrrole ( 2.66 g , 39.6 mmol ) under nitrogen. The mixture was stirred for 25 min at room temperature then $\mathrm{CH}_{2} \mathrm{Cl}_{2}(120 \mathrm{~mL})$ was added. The whole mixture was combined with aqueous NaOH ( 0.1 N .50 mL ). Then the organic layer was washed with water and dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$. Excess pyrrole was removed under reduced pressure and remaining black solid was purified by
column chromatography on silica (chloroform/hexanes, $8 /$ 2). Fast moving dipyrromethanes (major) which were formed by cleavage of tripyrromethane were eluted lirst then desired product was eluted. Yield $0.19 \mathrm{~g}(29 \%)$. (Higher yield upto $80 \%$ was obtained when the reaction was carried out at $0^{\circ} \mathrm{C}$ in the presence of 2 mM of $\mathrm{BF}_{3}$ ). ' $\mathrm{H} / \mathrm{NMR}$ $\left(\mathrm{CDCl}_{3}\right) \delta 7.93$ (bs, $2 \mathrm{H}, \mathrm{N}-\mathrm{H}$ ), 7.76 (bs, $\left.1 \mathrm{H}, \mathrm{N}-\mathrm{J} \mathrm{I}\right), 7.61$ and 6.92 (two doublets, $J-8.3 \mathrm{~Hz}, 4 \mathrm{H}, \wedge \mathrm{r}-\mathrm{H}$ ), $7.32-7.16$ (m, $511, \wedge r-1[), 6.68$ (dd, 2 H , pyrrole-I $), 6.13$ ( $\mathrm{m}, 2 \mathrm{H}$, pyrrolc1[) 5.87 (d, 1II, pyrrole-1[), 5.83 (d, 1H , pyrrole-H), 5.76 (t, 111, pyrrole-11), 5.73 (t. 1H, pyrrole-H), 5.37 ( $\mathrm{s}, 11 \mathrm{I}$, meso1[). 5.30 ( $s$, 111, meso-HI). HRMS Caled for $\mathrm{C}_{22} \mathrm{H}_{26}\left[\mathrm{~N}_{3}\right.$ 503.0858, Found 503.0877.

Porphyrin (7a), (8a) and (9a). Tripyrromethane (5) $(0.30 \mathrm{~g}, 0.60 \mathrm{mmol})$ and ( 6 a ) $(0.17 \mathrm{~g} .0 .60 \mathrm{mmol})$ were dissolved in chloroform ( 60 mL ), then $\mathrm{BF}_{3} \cdot \mathrm{OE}_{2}(147 \mu \mathrm{~L}, 1.20$ mmol) was added. The mixture was stirred at room temperature for 25 min then triethylamine ( 1.5 mL ) and DDQ ( 0.40 $\mathrm{g}, 1.80 \mathrm{mmol}$ ) were added at onee. The mixture was stirred for 1 hr at room temperature. The remaining solid material was removed by liltration. Evaporation of the solvent under reduced pressure and vaccum drying afforded the black solid which was purified by column chromatography on silica (ClICl $3_{3}$ TLIF, 9/1). The fast moving fraction was porphyrin (9a) (22 mg, 5\%). Sccond moving band was identified as porphyrin (8a) ( $67 \mathrm{mg}, 15 \%$ ). The last moving band was porphyrin (7a) (25 mg, 5\%). 'II NMR (CDCl $)$; For (7a): $\delta$ 9.17 (s. 2ll, furan-HI), 8.87 ( $\mathrm{s}, 2 \mathrm{H}$. pyrrole-[I), 8.57 (q. 41I, pyrrole-HI), 8.19-8.17 (m, 8II, Аr(o)-[I), 7.77-7.73 (m, 12HI, $\mathrm{Ar}-\mathrm{HI}$ ). IIRMS Calcd for $\mathrm{C}_{44}\left[\mathrm{H}_{29} \mathrm{~N}_{3} \mathrm{O}\right.$ 616.2389, Found 616.2413. For (8a): $\delta 9.18$ ( $\mathrm{s}, 2 \mathrm{I}$, furan-I $), 8.89$ and 8.86 (two doublets, 2ll, pyrrole-lI), 8.60 (dd, 2ll, pyrtole-ll), 8.54 (dd, 2ll, pyrrole-1[), 8.19-8.16 (m, 6H L, $\mathrm{Ar}(\mathrm{o})$-H $), 8.08-$ 7.91 (two doublets, 4lI. Ar-ll). 7.81-7.72 (m, 9]I, Ar-ll), -1.58 (bs. 111, $\mathrm{N}-\mathrm{H}$ ). l[RMS Calcd for $\mathrm{C}_{44} \mathrm{H}_{28} \mathrm{IN}_{3} \mathrm{O}$ 742.1355 , Found 742.1393. For (9a): $\delta 9.19$ (s, 2HI, furan1[), 8.87 (s, 2II, pyrrole-HI). 8.59 and 8.55 (two doublets, 4II, pyrrole-HI). 8.18-8.16 (m. $4 \mathrm{HI}, \mathrm{Ar}(\mathrm{O})-\mathrm{FI}$ ), 8.09-7.90 (two doublets, $8 \mathrm{II}, \mathrm{Ar}-\mathrm{HI}$ ), $7.80-7.73$ (m, $6 \mathrm{H}, ~ \wedge \mathrm{r}-\mathrm{H}$ ), -1.62 (bs, $\mathrm{HI}, \mathrm{N}-$ 15). IHRMS Calcd for $\left.\mathrm{C}_{44} \mathrm{I}_{27}\right]_{2} \mathrm{~N}_{3} \mathrm{O}$ 868.0322, Found 868.0364.

Porphyrin (7b), (8b) and (9b). Tripytromethane (5) ( $0.30 \mathrm{~g}, 0.60 \mathrm{mmol}$ ) diol ( 6 b ) ( $0.18 \mathrm{~g}, 0.60 \mathrm{mmol}$ ) and $\mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}(147 \mu \mathrm{~L}, 1.20 \mathrm{mmol})$ were treated identically as for the synthesis of 7a. Column chromatography on silica (chloroformhexanes, 7/3) gave good separation of three porphyrins; The fast moving fraction was porphyrin (9b) (22 $\mathrm{mg} .5 \%$ ). Second moving band was identilied as porphyrin ( 8 b) ( $68 \mathrm{mg}, 15 \%$ ). The last moving band was porphyrin (7b) (22 mg. 5\%). ${ }^{1} \mathrm{H}$ NMR (CDCly) for ( $\mathbf{8 b}$ ); $\delta 9.76$ (s, 2 HI , thiophene-HI), 8.95 (dd, 1I1, pyrrole-H), 8.91 (dd, 11I, pyr-role-1[), $8.69(\mathrm{dd}, 2 \mathrm{Il}, J-4.7 \mathrm{ll} 2$, pyrrole-H), $8.60(\mathrm{dd}, 2 \mathrm{H}$, $J-4.7 \mathrm{~Hz}$, pyrrole-H1). 8.26-8.24 (m, $4 \mathrm{H}, \mathrm{Ar}(\mathrm{o})-\mathrm{H})$ ), $8.21-$ 8.18 (m. $2 \mathrm{ll}, \mathrm{Ar}-\mathrm{I}$ ) .8 .09 and 7.94 ( 1 wo doublets, $4 \mathrm{II}, J-5.0$ 1[ц, Ar-][), 7.84-7.75 (m, 9I1, Ar-1[), -2.73 (bs, 1H, N-H). l[RMS Calcd for $\mathrm{C}_{44} \mathrm{H}_{28} \mathrm{IN}_{3} \mathrm{~S} 757.1049$, Found 757.1070 . ## Results and Discussion

Tripyrromethane 5 was synthesized from the condensation of alcohol 4 with pyrrole in the presence of $\mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}$ as shown in Scheme 2. GC-Mass analysis of the crude product indicated the formation of small amount of $N$-confused tripyrromethane. But the fraction of the $N$-confused tripyrromethane is quite small. Proton and carbon NMR spectra indicated that no diastereomeric mixture of 5 was fomed in the reaction. But dipyrromethanes were isolated when the reaction ran with extended time. The formation of dipyrromethanes indicates the cleavage of tripyrromethanes under high acid concentration with longer reaction time.

The tripyrromethane 5 also could be obtained as a minor product from dipyrromethane synthesis developed previously. ${ }^{11}$ The tripyrromethane was isolated by column chromatography of the residual black material after isolating dipyrromethane by vacuum distillation. The traditional condensation of 5 with $6 \mathbf{a}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ in the presence of $\mathrm{BF}_{5}$ ctherate resulted in the formation of three porphyrins 7a, 8a and 9a. The formation of 7a and 9a indicates that the reversible cleavage of the tripyrromethane 5 occur during the condensation. These results also indicate that nucleophilic attack of the pyrrole to the cationic center of luranyl $\alpha$-position (after dehydration) is possibly faster than acid-catalyzed cleavage of tripyrromethane. Similar condensation of 5 with $\mathbf{6 b}$ also alforded three porphyrins $\mathbf{7 b}, \mathbf{8 b}$ and $\mathbf{9 b}$. The identity of the three porphyrins isolated form each reactions was easily determined by proton NMR and high resolution mass spectrometry (lRMS) due to large difference in molecular weight and their diflerent symmetric character. The proton NMR spectra were shown in Figure 1. The integration and

Figure 1. $400 \mathrm{MHz}{ }^{\prime} \mathrm{H}$ NMR spectra of the three porphyrins 7 a (top), 8 a (mid) and 9 a (bottom) formed from the condensation of 5 and 6 a .
symmetry of each porphyrins clearly indicated the presence of the number of the $p$-iodophenyl group.

In order to avoid reversible cleavage of tripyrromethane during the condensation, we decided to adapt the low serambling conditions developed by Lindsey et al. ${ }^{\text {t }}$ in the condensations. The rapid small scale assay of the products using LD-MS enables to identily the degree of scrambling. Thus, we applied the same method in this study to survey conditions and suitable catalysts in the $3 \cdot 1$ condensations. The lirst condensation we atempted was use of $\mathrm{BEt}_{3}$ as alternative catalyst. As shown in Scheme 3, the attempled condensation of in $\mathrm{ClHCl}_{s}$ gave clean reaction without any evidence of scrambling. Although the yields were somewhat lower (5$15 \%$ ) than other condensations (data not shown), higher concentration of acid up to 30 mM didnt result in the cleavage of tripyrromethane.

These results indicate that the reaction catalyzed by triethylborane can be used in the synthesis of porphyrins without scrambling. Acid concentration giving unscrambled porphyrin product was as high as 50 mM . This remarkable stability of tripyrromethanes under such a large amount of acid present indicates that the triethylborane is an excellent cata-

Scheme 3
lyst for the porphyrin forming reaction.
The yields of porphyrin over variation of reactant coneentration ( 1.10 and 50 mM ) were monitored from 1 min to 90 min as shown in Figure 1. The yield of porphyrin reached a maximum within 5 min at 10 mM reactant concentration. There was no catalytic activity of acid when 1 mM of $\mathrm{BF}_{3} \cdot \mathrm{OEl}_{2}$ was applied. Higher concentration of acid also gave adversary effect on the yield of porphyin. Figure 2 showed the dependence on yield when $p$-TsOll was applied

Figure 2, Dependence of the spectroscopic yields on the concentration of reactants (tolyl-TPM and diol) in acetonitrile catalyzed by $\mathrm{BF}_{3}$ OEt 2 and PTSA. तo scrambling was detected by 1.D-MS for the conditions applied.

Figure 3. Itfect of inorganic salts on the condensation of tolylTPM ( 10 mM ) and diol $(10 \mathrm{mM})$ in acetonitrile catalyzed by $\mathrm{BI} ;(2$ mM ).
for catalyst. $\wedge$ pplication of $p-\mathrm{TsO}[$ [ gave higher yield of porphyrin at low acid concentration ( 1 mM ) as shown in Figure 2. The beneficial effects of the added inorganic salts on the yield of porphyrin were reported in the pyrrole-aldehydes and 212 condensation. ${ }^{8}$ Sinee the best result of salt effeet has been reported when combined with $\mathrm{BF}_{3}$, we examined the salt effect by performing reactions at 10 mM of reactants in the presence of various salts (Figure 3 and Figure 4). The yields were almost independent of added salts and LiCl and $\mathrm{Cs}_{2} \mathrm{CO}$ : seemed to somewhat deactivate the catalyst. Best yield was obtained when 100 mM of KCl or $\mathrm{NH}_{4} \mathrm{Cl}$ were applied. Thus, the low scrambling conditions identified in the $2 \cdot 2$ condensation can be generally applied for the synthesis of porphyrins with little scrambling: for example 10 mM of reactants in acetonitrile at $0^{\circ} \mathrm{C}$ in the presence of $\mathrm{NJ}_{4} \mathrm{Cl}(100 \mathrm{mM})$ catalyzed by $\mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}(1 \mathrm{mM})$.

The spectroscopic yields and extent of scrambling were not changing with reaction time. Optimized reaction showed an initial burst of porphyrin formation within a few minutes of the reaction. The reaction was faster when heteroatoms $(O, S)$ were present in the reactants. The oxaporphyrins are significantly more basic than regular porphyrins. ${ }^{9}$ In conclusion, we have shown that the 311 condensation of tripyrromethane with diol also a good methods for the synthesis of cis-substituted porphyrins. The low scambling conditions can be applied in $3 \cdot 1$ condensation even if the yields were somewhat lower than 212 condensation.

Acknowdedgment. This work was supported from the

Figure 4. Dependence of the spectroscopic yield on the concentration of reaclant in the presence of $\mathrm{NH} \mathrm{l}_{4} \mathrm{Cl}(100 \mathrm{mM})$ catalyzed by acids.
