

Putative Histone H2A Genes from a Red Alga, *Griffithsia japonica*

Yoo Kyung Lee* and Hong Kum Lee

National Research Lab for Marine Microbial Diversity, Korea Ocean Research and
Development Institute, Ansan P.O. Box 29, Seoul 425-600, Korea

Histones are important proteins that interact with the DNA double helix to form nucleosome. Two putative histone genes, *GjH2A-1* and *GjH2A-2* were isolated from a red alga *Griffithsia japonica*. The putative open reading frame of *GjH2A-1* and *GjH2A-2* shared high similarity with the previously reported amino acid sequences of histone H2As. They have a motif consisting of seven amino acids A-G-L-Q-F-P-V, which matches the histone H2A motif [AC]-G-L-x-F-P-V. Phylogenetic trees were constructed from amino acid sequences of 38 histone H2As. The histone H2As were divided into two groups: major H2As and H2A.F/Z variants. The major histone H2A group consisted of animals, fungi, plants + green algae, and red algae H2A subgroups. The animal histone H2A subgroup was divided into vertebrates, echinoderms, nematodes, insects, and segmented worms H2As. The putative red algal histone genes, *GjH2A-1* and *GjH2A-2*, constituted an independent lineage. This is the first report on red algal histone genes.

Key Words: EST(expressed sequence tag), *Griffithsia japonica*, Histone

INTRODUCTION

Histones are small, basic proteins that interact with the DNA double helix to form nucleosomes (McGhee and Felsenfeld 1980). There are five classes of histone proteins: H1, H2A, H2B, H3, and H4. The four core histones (H2A, H2B, H3 and H4) form an octameric assembly around which 146 base pairs of DNA wraps to form nucleosome (Kornberg and Thomas 1974). Histone H1 binds to the linker DNA found between these nucleosomes, playing a role in the stabilization and formation of higher-order chromatin structure (Noll and Kornberg 1977). The core histones are highly conserved across their entire sequences (Thatcher and Gorovsky 1994), therefore the histone sequences can be used as molecular markers for classification of higher hierarchy.

The total number of histone genes in a species is variable. For example, the genomic sequence of *Saccharomyces cerevisiae* includes two genes for each histone (Goffeau *et al.* 1996). *Aspergillus nidulans* has single genes encoding H2A, H2B, and H3 and two genes encoding slightly different H4 proteins (Ehinger *et al.* 1990). On the other hand, sea urchin has a few hundred

copies of histone genes (Ingham and Davis 1988). The histone genes are organized into tandemly repeating quintets of the five histones (Melfi *et al.* 2000), formed into one or two large clusters (Wang *et al.* 1996), or dispersed throughout the genome in small groups of one to few copies (Roberts *et al.* 1987). For most histones are encoded by multigene families (Chaboute *et al.* 1993), classification of histone gene families is important for their taxonomic application as molecular markers.

In this study, we report two putative histone H2A genes of a red alga *Griffithsia japonica*. We also examine phylogenetic relationship of histone H2As and their potentiality as a molecular marker.

MATERIALS AND METHODS

Strains and culture conditions

Griffithsia japonica was collected from Dolsan Island on the southern coast of Korea on 3 April, 1992, and cultured as described in a previous paper (Lee *et al.* 1995). The samples were blotted with paper towel to remove extra moisture, quickly frozen in liquid nitrogen, and stored at -70°C until they were used.

Construction of cDNA library

Total RNA was extracted from *G. japonica* using the

^a GenBank information number

TRI reagent (Molecular Research Center, Inc. USA). Poly(A)⁺ RNA was isolated using the polyATtract mRNA isolation kit (Promega, USA) according to the manufacturer's manual. After electrophoresis of 50 μ g mRNA, the fragments with size \geq 500 bp were purified from the agarose gel. The cDNA library was constructed from the purified mRNA using ZAP-cDNA Gigapack III Gold Cloning Kit (Stratagene, USA) according to the manufacturer's manual.

Excision and sequencing

The cDNA library was excised using ExAssist helper phage (Stratagene, USA). Each monoclonal containing *G. japonica* cDNA was cultured in 3 ml LB, and plasmid DNA containing *G. japonica* cDNA was extracted with AccuPrep plasmid Extraction Kit (Bioneer, Korea). The purified plasmid DNA was sequenced with T3 or T7 primers using an ABI PRISM 3100 Genetic Analyzer (Applied Biosystems, USA). Vector masking, contig assembly, and Blast search were performed using

Fig. 1. Nucleotide and deduced amino acid sequences of *GjH2A-1* and *GjH2A-2*. Nucleotide numbers are on the left side and the amino acid numbers are on the right side. Putative termination codons are marked by asterisk(*). Putative polyadenylation signals are underlined.

GeneMaster version 2.0 (Ensoltek, Korea). Two cDNA clones for putative histone H2A genes were selected after random sequencing and similarity analysis.

Phylogenetic analysis

Histone H2A amino acid sequences were obtained from the histone sequence database (Sullivan *et al.* 2002; <http://genome.nhgri.nih.gov/histones/>). Partial sequences, overlapped sequences, or long sequences were eliminated from the database. Total 38 histone H2A sequences of major eukaryotic organisms were finally selected (Table 1). The selected histone H2A sequences were aligned using CLUSTAL-X (Thompson *et al.* 1997), and final alignment was checked by visual inspection. Phylogenetic analyses were conducted using MEGA version 2.1 (Kumar *et al.* 2001). Phylogenetic trees were reconstructed from the distances using the ML-distance

(minimum evolution) method using Poisson correction model. Bootstrap consensus tree was obtained with 1,000 replicates.

GenBank accession numbers

Protein sequences of *G. japonica* histones were deposited in GenBank under the accession numbers AAP80715 (gi 32401019) and AAP80716 (gi 32401021).

RESULTS & DISCUSSION

Two putative histone genes of *G. japonica* were isolated, and designated as *GjH2A-1* and *GjH2A-2*. Nucleotide sequences of *GjH2A-1* and *GjH2A-2*, and their deduced amino acid sequences were determined (Fig. 1). Putative open reading frames for 124 amino acids started from the 5' end of the cDNA. Both *GjH2A-1* and *GjH2A-2* have

Fig. 2. Sequence alignment of the histone H2As from representative species. Numbers in parentheses are sequence identities with *Griffithsia japonica* 1 (*GjH2A-1*). Residues identical to all the sequences are marked by asterisks (*). Residues reflecting conservative changes are indicated by colons (:). Residues indicating the histone H2A motif [AC]-G-L-x-F-P-V are marked with shadow. Gaps were introduced to optimize the alignments, and gaps are represented by dashes (-), which indicates one amino acid.

putative polyadenylation signals with the consensus sequence of AATAAA. They have short 3' UTR (untranslated region), which reported from other *G. japonica* genes (Lee *et al.* 1998, 2002)

G/C content of *GjH2A-1* and *GjH2A-2* was 60.0% and 51.9% in the coding region, which is similar with other *G. japonica* genes previously reported (Lee *et al.* 1998, 2002). In the codon usage, *GjH2A-1* was strongly biased to G and C in the third position: 81.6% of the third position in the codon was G or C, which is similar with other *G. japonica* genes previously reported (Lee *et al.* 1998, 2002). Strong bias toward C or G in the third base of codons was also reported in human and mouse histone genes (Marzluff *et al.* 2002).

The *GjH2A-1* and *GjH2A-2* shared high similarity with

the previously reported amino acid sequences of histone H2As: the ORF shared 71-81% amino acid sequence identities to histones of representative animals, plants, fungi and green algae (Fig. 2). They also have a motif consisting of seven amino acids A-G-L-Q-F-P-V, which matches the histone H2A motif [AC]-G-L-x-F-P-V.

Phylogeny shows that the histone H2As are divided into two groups: major histone H2A and histone H2A.F/Z variants (Figs 3-4). These tree topologies agree with previous phylogenetic analysis of histone H2A (Thatcher and Gorovsky 1994). The histone H2A.F/Z variants are more closely related to each other than to the major H2As from the same species (Thatcher and Gorovsky 1994).

The tree topology of major histone H2A except of

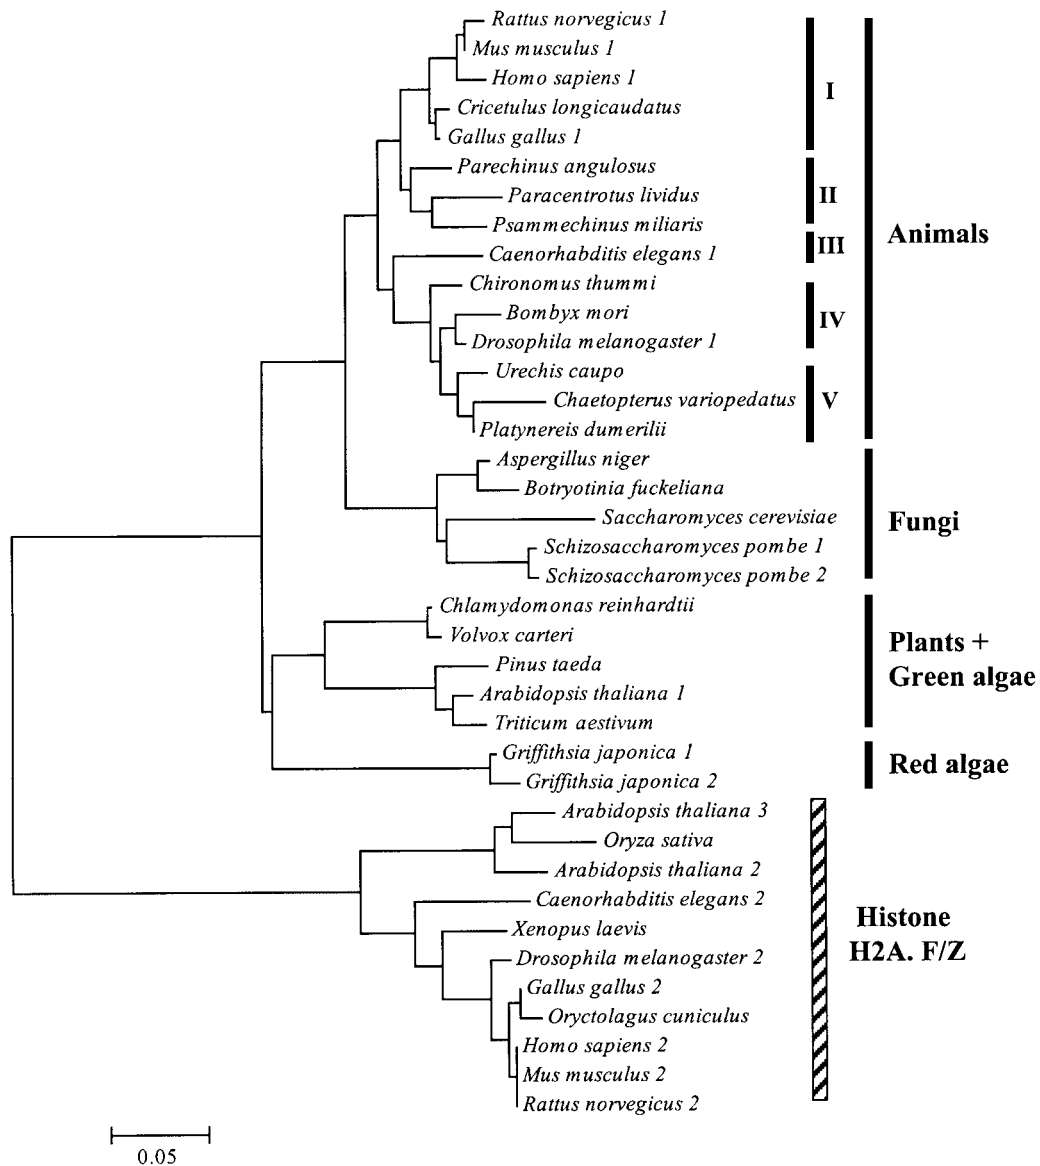

Fig. 3. Phylogeny of histone H2A amino acid sequences from representative species. Thirty-eight histone H2A sequences were selected from histone database, aligned and used to construct a minimum evolution tree (see Materials and Methods). The scale bar indicates the branch length that corresponds to 0.05 substitutions per position. The histone H2As are divided into two monophyletic groups: major H2As and H2A.F/Z variants. The major histone H2As consist of animals, fungal, plants + green algal, and red algal H2A subgroups. The animal histone H2A is divided into vertebrates (I), echinoderms (II), nematodes (III), insects (IV) and segmented worms (V) histone H2As.

H2A.F/Z variants are very similar to a eukaryotic phylogeny based on SSU rDNA sequences (Wainright *et al.* 1993). Animals, plants, fungal and red algal histone H2As form monophyletic group, respectively (Figs 3-4). The animal histone H2A has vertebrates (I), echinoderm (II), nematodes (III), insects (IV) and segmented worms (V) histone H2As (Figs 3-4). The closest relative *GjH2A-1* and *GjH2A-2* of is plants and green algal histone H2A (Fig. 3). But they can align with animal and fungal lin-

eage in other phylogenies (data not shown). Bootstrap consensus tree shows that the *GjH2A-1* and *GjH2A-2* make an independent lineage (Fig. 4). More data on red algal histone H2A sequences will decipher the relationship of red algal H2A and other eukaryotic H2As.

Because the topology of major histone H2A phylogeny is similar to the eukaryotic phylogeny based on SSU rDNA sequences, histone H2A can be used as a molecular marker for classification of higher hierarchy. But for

Fig. 4. Bootstrap consensus tree with bootstrap values (% of 1,000 replications) showing relationships between 38 histone H2As with 159 amino acid positions. The major histone H2As consist of animals, fungal, plants + green algal, and red algal H2A groups. The animal histone H2A is divided into vertebrates (I), echinoderms (II), nematodes (III), insects (IV), and segmented worms (V) histone H2As. The histone H2A.F/Z variants consist of animal, plant, and nematode H2A.F/Z. The *GjH2A-1* and *GjH2A-2* make an independent lineage.

histone H2A contains F/Z variants, pseudogenes and macroH2A genes (DeBry 1998; Jiang *et al.* 1998; Pehrson and Fuji 1998), we have to be careful to select genes in the same subfamily to use histone H2A as molecular marker.
