Selected paper from APIEM 2006

**Abstract.** The bin packing problem (BPP) is an NP-Complete Problem. The problem can be described as there are  $N = \{1, 2, \dots, n\}$  which is a set of item indices and  $L = \{s_1, s_2, \dots, s_n\}$  be a set of item sizes  $s_j$ , where  $0 < s_j \leq 1, \forall j \in N$ . The objective is to minimize the number of bins used for packing items in  $N$  into a bin such that the total size of items in a bin does not exceed the bin capacity. Assume that the bins have capacity equal to one. In the past, many researchers put on effort to find the heuristic algorithms instead of solving the problem to optimality. Then, the quality of solution may be measured by the asymptotic worst-case ratio or the average-case ratio. The First Fit Decreasing (FFD) is one of the algorithms that its asymptotic worst-case ratio equals to  $11/9$ . Many researchers prove the asymptotic worst-case ratio by using the weighting function and the proof is in a lengthy format. In this study, we found an easier way to prove that the asymptotic worst-case ratio of the First Fit Decreasing (FFD) is not more than  $11/9$ . The proof comes from two ideas which are the occupied space in a bin is more than the size of the item and the occupied space in the optimal solution is less than occupied space in the FFD solution. The occupied space is later called the weighting function. The objective is to determine the maximum occupied space of the heuristics by using integer programming. The maximum value is the key to the asymptotic worst-case ratio.

**Keywords:** The Bin Packing Problem, Heuristic, Asymptotic Worst-case Ratio, Maximum Occupied Space

## 1. INTRODUCTION

In a Bin Packing Problem (BPP), let  $N = \{1, 2, \dots, n\}$  be a set of item indices and  $L = \{s_1, s_2, \dots, s_n\}$  be a set of item sizes  $s_j$ , where  $0 < s_j \leq 1; \forall j \in N$ . The objective is to minimize the number of bins used for packing items in  $N$  into a bin such that the total size of items in a bin does not exceed the bin capacity. Assume that the bins have capacity equal to one. According to Garey and Johnson (1979) and Coffman *et al.* (1997), a BPP is an NP-Complete Problem. We review some traditional heuristics for the BPP. Each algorithm indexes bins  $\{1, 2, \dots, n\}$  in the order they are opened.

## 2. LITERATURE REVIEW

The research focuses on the unit-capacity bin packing problem and the First Fit Decreasing (FFD) algorithm. First, Johnson *et al.* (1974), and Johnson (1973) show that the asymptotic worst-case performance ratio for First Fit (FF) and Best Fit (BF) is not more than  $17/10$ , and not more than  $11/9$  for either FFD or Best Fit

Decreasing (BFD). They prove that  $FFD(L) \leq 11/9 OPT(L) + 4, \forall L$ , where  $L$  is a list of items in the BPP,  $OPT(L)$  is the minimum required number of bins for a list  $L$ , and  $FFD(L)$  is the number of bins used by the FFD heuristic. They use a weighting function to show the worst-case performance of these heuristics. The weighting function depends on the item sizes and the packing location.

Later, Baker (1983) proves the theorem that  $FFD(L) \leq 11/9 OPT(L) + 3, \forall L$ . In his proof, he partitions the last item size into subintervals, and proves that each subinterval does not violate the theorem by the weighting function. He shows that in the FFD bins, an item of size greater than one third requires the same number of bins as would the optimal solution. Moreover, an item of size strictly less than  $2/11$  automatically satisfies the theorem. This reduces the length of the proof by considering only four intervals of the size of the last item in a list  $L$ .

Frisen and Langston (1991) use a new technique called the weighting function averaging to prove the worst-case performances of FFD and B2F (Best two Fit) algorithms which are equal to  $11/9$  and  $5/4$ , respectively.

---

<sup>†</sup> : Corresponding Author

They propose a compound algorithm, which combines both FFD and B2F algorithms in regions in which they are superior. Then, they prove by using a weighting function whose worst-case performance is no greater than 6/5. They shorten the length of the proof by reducing the size of the last item to an interval of (1/6, 1).

Yue (1991) proposes a simpler proof and provides a tighter bound with  $FFD(L) \leq 11/9 OPT(L) + 1, \forall L$ . The proof is based on a weighting function and minimal counter example. He shows that the counter example does not exist for his theorem. In addition, he reduces the number of intervals of the size of the last item to three which is similar to the work of Baker.

### 3. THEOREM AND PROOF

**Theorem 1**  $\lim_{z(L) \rightarrow \infty} \frac{z^H(L)}{z^*(L)} \leq \frac{11}{9}$ , and the ratio is tight.

Theorem 1 implies that the total number of bins generated by the FFD is not more than 22.22 % more bins than the number of optimal bins for BPP.

#### 3.1 Preliminary

In this section, we present properties and lemmas to support the proof of Theorem 1. We will prove Theorem 1 by contradiction. Suppose there exists a list that violates the theorem. Let  $L$  be a minimum list that violates the theorem. That is  $z^H(L) > 11/9 z^*(L)$ , but  $z^H(L) \leq 11/9 z^*(L)$ , for  $L' \subset L$ . Define  $z^*(L)$  be the minimum number of bins used to pack items in a list  $L$  and  $z^H(L)$  be the number of bins used by FFD algorithm to pack items in a list  $L$ . Define  $J_b$  be a set of items in any FFD bin  $b = 1, \dots, z^H(L)$  and  $J_b^*$  be a set of items in any optimal bin  $b = 1, \dots, z^*(L)$ . However, we will call  $J$  and  $J^*$  for the short notation of any FFD bin and optimal bin, respectively. After sorting items in a list  $L$ , let  $s_i$  be the size of the item  $i^{th}$  and  $s_n$  be the size of the last item. Then, we propose the following lemmas to support the proof.

**Lemma 1:** For all  $b = 1, 2, \dots, z^H(L)-1$ , we have that  $|J_b| \geq 2$ .

**Proof:** Consider a list  $L$  using exactly  $d+1$  bins in FFD. Suppose  $J_b = \{j\}$  for some  $b = 1, 2, \dots, d$ . Then,  $s_j + s_n > 1$ . Thus,  $J_e^* = \{j\}$  for some  $e = 1, 2, \dots, z^*$ . First, remove item  $j$  from a list  $L$  and call the new list  $L'$ . Then,  $z^*(L) = z^*(L') - 1 \leq 9/11 z^H(L') - 1 \leq 9/11 (z^H(L) - 1) - 1 \leq 9/11 z^H(L) - 2/11$ . Hence, contradict with  $L$ , in which it is a minimum list that violates Theorem 1.  $\square$

**Lemma 2:** For all  $b = 1, 2, \dots, z^*(L)-1$ , we have that  $|J_b^*| \geq 3$ .

**Proof:** The proof is done by Yue (1991).  $\square$

Next, we partition the range of the size of the last item ( $s_n$ ) into five ranges as follows:

1. If  $s_n > 1/3$ , then  $z^H(L) = z^*(L)$ . Since  $s_n > 1/3$ , implies  $|J_b^*| \leq 2$ . Combine with Lemma 1, it implies  $z^H(L) = z^*(L)$ .  $\square$
2. If  $s_n < 2/11$ , then  $z^H(L) \leq 11/9 z^*(L)$ . Since the item of size less than 2/11 cannot be packed in any previous bin before the last bin. This implies that the total content of any bin except the last bin must be less than 9/11. Then, the sum of the item sizes is at least  $9/11(z^H(L) - 1)$ . Then,  $z^*(L) \geq 9/11(z^H(L) - 1)$  or  $z^H(L) \leq 11/9 z^*(L) + 1$ .  $\square$
- For  $2/11 \leq s_n \leq 1/3$ , we partition into three ranges and we will proof this by using weighting function.
3. If  $1/6 < s_n \leq 1/5$ , then  $z^H(L) \leq 73/60 z^*(L)$ .
4. If  $1/5 < s_n \leq 1/4$ , then  $z^H(L) \leq 11/9 z^*(L)$ .
5. If  $1/4 < s_n \leq 1/3$ , then  $z^H(L) \leq 7/6 z^*(L)$ .

#### 3.2 The Maximum Occupied Space Technique

In this section, we present the maximum occupied space technique, using similar idea as the weighting function. In the literature, Johnson (1973), Johnson et al. (1974), Baker (1983), Frisen and Langston (1991) and Yue (1991) use the weighting function to prove the FFD worst-case performance of FFD. It shows that the weighting function is an effective method to prove the worst-case performance of an offline algorithm for the bin packing problem.

In the FFD packing, the actual size of the item does not indicate the space required for the packing. On the other hand, the weight of an item represents the space occupied by the item to pack in a bin. For example, if  $s_n = 1/6$  and one of the bins has three items each of size 2/7 with the total size of 6/7, then we assign the weight of these items to 1/3. It shows that each item occupies the equal space of 1/3 instead of 2/7. Notice that the weight of an item is not smaller than its size.

Let  $W(i)$  be the space occupied by an item  $i$ ,  $W(J_b)$  and  $W(J_b^*)$  be the space occupied by the FFD and optimal bin  $b$ , respectively. Similarly, define  $W(L)$  to be the total space occupied by items in a list  $L$ .

By the FFD rule, we define the types of the FFD bins as follows:

1. A Pure Bin. It is a bin containing only items of the same range ( $R_j$ ), which occurs only to a pure item ( $p_i$ -item), where a  $p_i$ -item is an item that is packed in a bin when all higher indexed bins are empty. There are  $i$  items of type  $p_i$  in  $J$ . The size of a  $p_i$ -item is determined so that FFD packs  $i$  items of  $p_i$  into a  $p_i$ -bin.
2. A Non-Pure Bin. It is a bin containing items of different ranges. There are two types of non-pure bins defined as follows:
  - 2.1 A Fallback Bin. It contains  $i$  items of non-pure items ( $n_i$ -item) and at least one fallback items, where a non-pure item is an item that is packed in a bin with smaller items. A fallback item is an item that

is packed in a bin when the higher indexed bin is not empty. There are two types of a fallback bin: an  $n_1$  bin containing a G item which is an item of size  $\geq 1/2$  and smaller items, and an  $n_i$  bin, for  $i \geq 2$  containing  $i$  items of  $n_i$  and one or more fallback items.

2.2 A Transition Bin. It is a bin containing the highest indexed item of any of item types except type  $n_1$ , i.e. it is the last FFD bin of each item type except G bin. The total number of transition bins is not more than the total number of the  $p_i$  and  $n_i$  types of bins.

For example,  $n_1$ -bin (G bin),  $p_2$ -bin, and  $n_3$ -bin represent the bins that contain  $n_1$ ,  $p_2$  and  $n_3$  as the first item in the bin, respectively. We call the occupied space for bin packing as the weight and assign the weight of the FFD bin so that the total weight in each bin is equal to one. To avoid the numerical values of the weight of different items, we unify the weight of the item type. For  $1/(m+1) < s_n \leq 1/m$ , where  $m = 3, 4, 5$ , the weight of the same item type is unique and follows the following rules:

1. If item  $j$  is of type  $p_i$ , then  $W(j) = 1/i$ .
2. If item  $j$  is of type  $n_1$  or G, then  $W(j) = 1-1/m$ .
3. If item  $j$  is of type  $n_i$ , for  $i > 1$ , then  $W(j) = (m-2)/(i*(m-1))$ .

Next, we define the ranges of item sizes for  $1/(m+1) < s_n \leq 1/m$  as follows:

1. To determine the maximum size of an item type  $n_1$  or G, by Lemma 2, we have  $|J^*_b| \geq 3$ . Thus,  $s_G < 1 - 2*s_n$ .
2. For a  $p_i$  item,  $1-s_n \leq i*s_{p_i} < 1, \forall i < m$ . Thus,  $(1-s_n)/i \leq s_{p_i} < 1/i$ .
3. For an  $n_i$  item  $s_{p_{i+1}} \leq s_{n_i} < s_{p_i}, \forall i = \{2, \dots, m-1\}$ .
4. The last range is  $s_n \leq s_{p_i} < s_{n_{i-1}}$ , for  $i = m$ .

Next, we define  $z^H = z^H(L)$  and  $z^* = z^*(L)$  and use these notation for the rest of the paper. Then, we derive the following lemma to proof Theorem 1:

**Lemma 3**  $\lim_{z^* \rightarrow \infty} \frac{z^H}{z^*} \leq W^M$ , where  $W^M$  is the maximum

occupied space of optimal bins.

**Proof:**

$$\sum_{b=1}^{z^H} W(J_b) = \sum_{b=1}^{z^*} W(J^*_b) = W(L) \tag{1}$$

$$z^H - A = \sum_{b=1}^{z^*} W(J^*_b) \leq W^M z^* \tag{2}$$

$$z^H \leq W^M z^* + A \tag{3}$$

Where  $A$  is a positive number. We need to show that  $W^M$  is equal to  $11/9$ .  $\square$

### 3.3 The Integer Program for the Maximum Space Occupied by the Optimal Bins

In this section, we adapt an integer program for the Open Bin Packing Problem by Ongkunaruk (2005) to show how to determine the maximum value of  $W(J^*_b)$  for the BPP. The objective is to determine the maximum occupied space of the optimal packing so that the total size of the items in a bin is not more than one. For  $1/(m+1) < s_n \leq 1/m$ , we can formulate the problem as follows:

Problem 1:  $\max \sum_i w(i)x_i$   
 $s.t. \sum_i LS_i(m)x_i \leq 1. \tag{4}$

$$x_i \geq 0, \text{ integer } \forall i \in \{n_j, p_{j+1}\} \forall j = \{1, \dots, m-1\}. \tag{5}$$

Where  $x_i$  is the number of item type  $i$  in  $J^*$  (See Ex.1),  $LS_i(m) \in LS(m)$ , where  $LS(m)$  is a set of the smallest size of item types, which is a function of  $s_n$ , and  $s_n$  is a function of  $m$ . Furthermore,  $W(i)$  is the occupied space function of an item type  $i$ . Constraint 4 requires that the total content of items in  $J^*$  must be  $\leq 1$ . Constraint 5 requires that the number of items of type  $i$  in  $J^*$  must be a positive integer. The objective is to determine the maximum occupied space in  $J^*$ . We need to modify the left hand side of Constraint 4 since the value of  $LS_i(m)$  depends on  $s_n \in (1/(m+1), 1/m]$ . Let  $LS_i(m) = a_i + b_i s_n$ . Then, consider the following two cases:

1. If  $b \geq 0$ , then we use the lower bound of  $s_n$  since

**Figure 1.** An example of the FFD packing that contains a  $p_2$  bin, a transition bin, a  $n_2$  bin, a  $p_3$  bin and the last bin, respectively.

$$\sum_i (a_i + b_i (\frac{1}{m+1} + \frac{1}{2\delta}) x_i) \leq \sum_i (a_i + b_i s_n x_i) \leq 1 \quad (6)$$

Where  $\delta$  is the least common factor of the denominators of LS(m), for  $s_n = 1/(m+1)$ .

2. If  $b < 0$ , then we use the upper bound of  $s_n$  since

$$\sum_i (a_i + b_i (\frac{1}{m}) x_i) \leq \sum_i (a_i + b_i s_n x_i) \leq 1 \quad (7)$$

If the lower bound of the size is not an exact value, we add the small value by using the least common factor of the denominators of LS(m). From these two cases, we can formulate an integer program by using  $s_n = 1/m$  and  $s_n = 1/(m+1) + 1/2\delta$ . Then, we select the maximum objective function or  $W(J^*_b)$  between two integer programs as shown in Example 1.

**Example 1:** An integer program for  $m = 3$  or  $1/4 < s_n \leq 1/3$ . The occupied space and sizes of items are in Table 1. First, if  $s_n = 1/3$ , then  $LS(3) = \{(1-1/3)/2 + 1/2\epsilon, 1/3 + 1/4\epsilon, 1/3\} = \{5/12, 3/8, 1/3\}$ , where  $\epsilon = 6$ . The integer program is as follows:

$$\begin{aligned} \max \quad & \frac{1}{2} x_{p_2} + \frac{1}{3} x_{n_2} + \frac{1}{3} x_{p_3} \\ \text{s.t.} \quad & \frac{5}{12} x_{p_2} + \frac{3}{8} x_{n_2} + \frac{1}{3} x_{p_3} \leq 1 \\ \text{or} \quad & 10x_{p_2} + 9x_{n_2} + 8x_{p_3} \leq 24 \end{aligned} \quad (8)$$

$$x_{p_2}, x_{n_2}, x_{p_3} \geq 0, \text{ integer} \quad (9)$$

Next, if  $s_n = 1/4 + 1/2\delta$ , where  $\delta = 2*3*4 = 24$ . Then,  $LS(3) = \{(1-13/48)/2 + 1/2\epsilon, 1/3 + 1/4\epsilon, 13/48\}$ , where  $\epsilon = 24$ . Thus,  $LS(3) = \{37/96, 11/32, 13/48\}$ , then Constraint 8 changes to

$$\frac{37}{96} x_{p_2} + \frac{11}{32} x_{n_2} + \frac{13}{48} x_{p_3} \leq 1 \quad (10)$$

After solving two problems, the optimal solution is

**Figure 2.** An example of the worst case example of FFD packing using 11N bins and optimal packing using 9N bins, where  $s_{m'} > s_m$

$J^* = (p_2, n_2, p_3)$  and  $W(J^*_b) = 7/6$ . The integer programs for  $m = 4$  and  $m = 5$  are shown in Appendix.

**Table 1.** Summary of item sizes and weight for  $1/4 < s_n \leq 1/3$ .

Items Types	Range of Item Sizes	Occupied Space
$p_2$	$((1-s_n)/2, 1/2]$	$1/2$
$n_2$	$(1/3, (1-s_n)/2)$	$1/3$
$p_3$	$(s_n, 1/3]$	$1/3$

### 3.4 The Proof of Theorem 1

In this section, we use Lemma 3 for the proof of  $1/6 \leq s_n \leq 1/3$ . We partition the range into three ranges. In each range, we derive the maximum occupied space as follows:

3.4.1 If  $1/4 < s_n \leq 1/3$ , then  $z^H(L) \leq 7/6 z^*(L)$

In this case, we have that  $|J^*_b| \leq 3$ . Combine this with Lemma 2, we have that  $|J^*_b| = 3$ . Since  $s_G + 2s_n > 1/2 + 2*1/4 = 1$ . Thus, G item is not in  $J^*$ . Table 1 shows item sizes and weight for  $1/4 < s_n \leq 1/3$ .

According to the FFD rule (see Figure 1), two items of item type  $p_2$ , two items of item type  $n_2$  with one item of type  $p_3$ , and three items of type  $p_3$ ; except the transition bins with the total weight  $\leq 3$ . Each of Other FFD bins has total occupied space equal to one. From the integer program, we have  $W^M \leq 7/6$ . Thus, we have

$$z^H - 3 \leq \frac{7}{6} z^*$$

$$z^H \leq \frac{7}{6} z^* + 3$$

$$\lim_{z^*(L) \rightarrow \infty} \frac{z^H(L)}{z^*(L)} \leq \frac{7}{6}$$

3.4.2 If  $1/5 < s_n \leq 1/4$ , then  $z^H(L) \leq 11/9 z^*(L)$

According to the FFD rule, an item of type G will be packed with one or two smaller items, two items of item type  $p_2$ , two items of item type  $n_2$  with one item of type  $p_3$  or smaller, three items of type  $p_3$ , three items of item type  $n_3$  with one item of type  $p_4$  and four items of

type  $p_4$ ; except the transition bins with the total weight  $\leq 5$ . Each of the remaining FFD bins has weight  $\geq 1$ . According to the size and weight in Table 2, we solve the integer program, and get the result as follows:

1. If there is no G item in a bin, then  $W^M \leq 7/6$  and  $J^* = (2p_3, 2p_4)$  or  $(2m, 2t)$ .
2. If there is a G item in a bin, then  $W^M \leq 4/3$  and  $J^* = (G, p_3, p_4)$  or  $(G, m, t)$ .

However, when there is a G item in a bin, some of the FFD bins also have total weight greater than one. Hence, we need to adjust the weight of the optimal bin by reducing its weight according to the extra space of the FFD bin. In short,

we subtract the weight of the optimal bin equal to the weight of the FFD bin that is greater than one.

**Table 2.** Summary of item sizes and weight for  $1/5 < s_n \leq 1/4$ .

Items Types	Range of Item Sizes	Occupied Space
G	$(1/2, 3/5]$	$3/4$
$p_2$	$((1-s_n)/2, 1/2]$	$1/2$
$n_2$	$(1/3, (1-s_n)/2)$	$3/8$
$p_3$	$((1-s_n)/3, 1/3]$	$1/3$
$n_3$	$(1/4, (1-s_n)/3]$	$1/4$
$p_4$	$[s_n, 1/4]$	$1/4$

Define a non G item of size  $\geq (1-s_n)/3$  as an item of type m (that is an item of type  $p_2, n_2$  or  $p_3$ ). Also, define a non G item of size  $< (1-s_n)/3$  as an item of type t (that is an item of type  $n_3$  or  $p_4$ ). In this case, we present the weight adjustment for the G bin. Let  $G_x^*$  be a set of items of type G packed with items of set X in J, but packed with items of set Y in  $J^*$ . For example, any item  $i \in G_{mt}^m$  implies an item i of type G is packed with an item of type m only in J, but packed with an item of type m and t in  $J^*$ . Since an item of type m is larger than that of type t, by the FFD rule,  $G_{mt}^i = \phi$  and  $G_{tt}^i = \phi$ . Next, consider the weight adjustment. For example, if a G item is packed with an item of type m and t in  $J^*$ , then  $W(J^*) \leq 4/3$ , but packed with m in J, then we can adjust  $1/12$  to the weight of the optimal bin. Then, consider the following adjustments:

1. For  $i \in G_{mt}^m$ ,  $W(J^*) \leq 4/3 - 13/12 + 1 = 5/4$ .
2. For  $i \in G_{mt}^t$ ,  $W(J^*) \leq 4/3 - 4/3 + 1 = 1$ .
3. For  $i \in G_{tt}^m$ ,  $W(J^*) \leq 4/3 - 5/4 + 1 = 13/12$ .
4. For  $i \in G_{tt}^t$ ,  $W(J^*) \leq 5/4 - 1 + 1 = 5/4$ .
5. For  $i \in G_{tt}^m$ ,  $W(J^*) \leq 5/4 - 13/12 + 1 = 7/6$ .
6. For  $i \in G_{tt}^t$ ,  $W(J^*) \leq 5/4 - 5/4 + 1 = 1$ .

In addition, we found that the worse packing of FFD is the combination of G bin and non G bin as

shown in Figure 2. Thus, the maximum weight is the average weight of the proportion of the weight of these bins. Consider the following property:

**Property 1:** A t item packed with  $i \in G_{tt}^t$  in the FFD solution cannot be packed with a G bin  $j \in G_{tt}^t$  in the optimal solution.

**Proof:** Suppose there exist such a packing, i.e. let  $i = G_1$  and the t item mentioned is  $t_2$ . Then,  $J_1^* = (G_1, t_1, t_1)$ ,  $J_2^* = (G_2, t_2, t_2)$ , and  $t_2$  packed with  $G_1$  only in the FFD packing, i.e.  $J_1 = (G_1, t_2)$  exists. Since  $t_2$  packed with  $G_1$  only, but packed with  $G_2$  and  $t_2$  in the optimal solution,  $s_{G_1} > s_{G_2}$ . Consider the FFD packing, there must exist an item k of type t packed with  $G_2$  in J must be too large to be packed with  $G_1$ , i.e.  $s_{G_1} + s_k > 1$ . Since,  $s_{G_1} < 1 - 2s_n$ , then  $s_k > 1 - s_{G_1} = 2s_n$ . If  $1/5 < s_n \leq 1/4$ , then  $s_k > 2/5$  contradicts with the size of  $t < (1-s_n)/3 = 1/4$ . In addition, if  $1/6 < s_n \leq 1/5$ , then  $s_k > 2/6$  contradicts with the size of  $t < (1-s_n)/3 = 4/15$ .  $\square$

Next, we consider the following possibilities:

1. If  $i \in G_{mt}^m \neq \emptyset$  and  $j \in G_{tt}^t = \emptyset$ , then an item of type m packed with i in the FFD packing must come from the optimal bin with weight  $\leq 7/6$ , in which at most two of i-bin packed with the bin containing the item of type m. Thus, the average can be calculated as follows:

$$W^M \leq \frac{2}{3} * \frac{5}{4} + \frac{1}{3} * \frac{7}{6} = \frac{11}{9}.$$

2. If  $i \in G_{mt}^m = \emptyset$  and  $j \in G_{tt}^t \neq \emptyset$ , then by Property 1, an item of type t packed with j in the FFD solution must come from the optimal bin with weight  $\leq 7/6$ . Thus, the average can be calculated as follows:

$$W^M \leq \frac{2}{3} * \frac{5}{4} + \frac{1}{3} * \frac{7}{6} = \frac{11}{9}.$$

3. If  $i \in G_{mt}^m \neq \emptyset$  and  $j \in G_{tt}^t \neq \emptyset$ , then the average cannot be greater than  $11/9$ . Since there must exist an item  $k \in G_{tt}^m$  with weight  $7/6$  packed with i and j and the non-G bins by at most the proportion of 2:2:2:1, respectively. Thus, the average can be calculated as follows:

$$W^M \leq \frac{4}{7} * \frac{5}{4} + \frac{3}{7} * \frac{7}{6} = \frac{17}{14} < \frac{11}{9}.$$

4. If  $i \in G_{mt}^m = \emptyset$  and  $j \in G_{tt}^t = \emptyset$ , then  $W^M \leq 7/6$ .

Thus, we have that

$$z^H - 5 \leq \frac{11}{9} z^*.$$

$$z^H \leq \frac{11}{9} z^* + 5.$$

$$\lim_{z^*(L) \rightarrow \infty} \frac{z^H(L)}{z^*(L)} \leq \frac{11}{9}.$$

3.4.3 If  $1/6 < s_n \leq 1/5$ , then  $z^H(L) \leq 11/9 z^*(L)$

According to the FFD rule, an item of type G will be packed with one or two smaller items, two items of item type  $p_2$ , two items of item type  $n_2$  with one item of type  $p_3$  or smaller, three items of type  $p_3$ , three items of item type  $n_3$  with a smaller item, four items of type  $p_4$ , four items of item type  $n_4$  with one item of type  $p_5$  and five items of type  $p_5$ ; except the transition bins with the total weight  $\leq 7$ . Each of the remaining FFD bins has weight  $\geq 1$ . According to the size and weight in Table 3, we solve the integer program, and get the result as follows:

1. If there is no G item in a bin, then  $W^M \leq 71/60$  and  $J^* = (p_3, p_4, 3p_5)$  or  $(m, 4t)$ .
2. If there is a G item in a bin, then  $W^M \leq 83/60$  and  $J^* = (G, p_3, p_4)$  or  $(G, m, t)$ .

Similar to the previous case, consider the following weight adjustments:

1. For  $i \in G_{mt}^m$ ,  $W(J^*) \leq 83/60 - 17/15 + 1 = 5/4$ .
2. For  $i \in G_{mt}^m$ ,  $W(J^*) \leq 83/60 - 4/3 + 1 = 21/20$ .
3. For  $i \in G_{mt}^m$ ,  $W(J^*) \leq 83/60 - 5/4 + 1 = 17/15$ .
4. For  $i \in G_{it}^m$ ,  $W(J^*) \leq 13/10 - 21/20 + 1 = 5/4$ .
5. For  $i \in G_{it}^m$ ,  $W(J^*) \leq 13/10 - 17/15 + 1 = 7/6$ .
6. For  $i \in G_{it}^m$ ,  $W(J^*) \leq 13/10 - 5/4 + 1 = 21/20$ .

**Table 3.** Summary of item sizes and weight for  $1/6 < s_n \leq 1/5$ .

Items Types	Range of Item Sizes	Occupied Space
G	$(1/2, 2/3]$	4/5
$p_2$	$((1-s_n)/2, 1/2]$	1/2
$n_2$	$(1/3, (1-s_n)/2)$	2/5
$p_3$	$((1-s_n)/3, 1/3]$	1/3
$n_3$	$(1/4, (1-s_n)/3]$	4/15
$p_4$	$[(1-s_n)/4, 1/4]$	1/4
$n_4$	$(1/5, (1-s_n)/4]$	1/5
$p_5$	$[s_n, 1/5]$	1/5

Similarly, we consider the following possibilities:

1. If  $i \in G_{mt}^m \neq \emptyset$  and  $j \in G_{it}^t = \emptyset$ , then an item of type m packed with i in the FFD packing must come from the optimal bin with weight  $\leq 71/60$ , in which at most one of i-bin packed with the bin containing the item of type m. Thus, the average can be calculated as follows:

$$W^M \leq \frac{1}{2} * \frac{5}{4} + \frac{1}{2} * \frac{71}{60} = \frac{73}{60} < \frac{11}{9}.$$

2. If  $i \in G_{mt}^m = \emptyset$  and  $j \in G_{it}^t \neq \emptyset$ , then by Property 1, an item of type t packed with j in the FFD solution must come from the optimal bin with weight  $\leq 71/60$ . Thus, the average can be calculated as follows:

$$W^M \leq \frac{1}{2} * \frac{5}{4} + \frac{1}{2} * \frac{71}{60} = \frac{73}{60} < \frac{11}{9}.$$

3. If  $i \in G_{mt}^m \neq \emptyset$  and  $j \in G_{it}^t \neq \emptyset$ , then the average cannot be greater than 11/9. Since there must exist an item  $k \in G_{it}^m$  with weight 7/6 packed with i and j and the non-G bins by at most the proportion of 2:2:2:1, respectively. Thus, the average can be calculated as follows:

$$W^M \leq \frac{4}{7} * \frac{5}{4} + \frac{2}{7} * \frac{7}{6} + \frac{1}{7} * \frac{71}{60} = \frac{73}{60} < \frac{11}{9}.$$

4. If  $i \in G_{mt}^m = \emptyset$  and  $j \in G_{it}^t = \emptyset$ , then  $W^M \leq 71/60$ .

Thus, we have that

$$z^H - 7 \leq \frac{73}{60} z^*.$$

$$z^H \leq \frac{73}{60} z^* + 7.$$

$$\lim_{z^*(L) \rightarrow \infty} \frac{z^H(L)}{z^*(L)} \leq \frac{73}{60}.$$

From all cases, there is no list L that violates Theorem 1. This completes the proof.

## 4. CONCLUSION

In the past, the asymptotic worst-case ratio of heuristics for the bin packing problem (BPP) has been proved to show the quality of those heuristics. The First Fit Decreasing (FFD) is one of the algorithms that its asymptotic worst-case ratio equals to 11/9. Many researchers prove the asymptotic worst-case ratio by using the weighting function in a lengthy format. In this study, we shorten the proof from two ideas. First, the occupied space in a bin is more than the size of the item. Second, the occupied space in the optimal solution is less than occupied space in the FFD solution. The occupied space is equivalent to the weighting function. The objective is to determine the maximum occupied space of the heuristics by using integer programming with a limited number of variables and constraints. Then, the maximum ratio is derived by matching items case by case as shown in previous section.

## APPENDIX

### An integer program for $1/5 < s_n \leq 1/4$ as the occupied space and sizes of items in Table 2.

First, if  $s_n = 1/4$ , then  $LS(4) = \{1/2+1/2\varepsilon, (1-1/4)/2+1/2\varepsilon, 1/3+1/4\varepsilon, (1-1/4)/3+1/2\varepsilon, 1/4+1/8\varepsilon, 1/4\} = \{25/28,$

$19/28, 33/96, 13/48, 49/192, 1/4\}$ , where  $\varepsilon = 24$ . The integer program is as follows:

$$\begin{aligned} \max \quad & \frac{3}{4}x_G + \frac{1}{2}x_{p_2} + \frac{1}{3}x_{n_2} + \frac{1}{3}x_{p_3} + \frac{1}{4}x_{n_3} + \frac{1}{4}x_{p_4} \\ \text{s.t.} \quad & \frac{25}{48}x_G + \frac{19}{48}x_{p_2} + \frac{33}{96}x_{n_2} + \frac{13}{48}x_{p_3} + \frac{49}{192}x_{n_3} + \frac{1}{4}x_{p_4} \leq 1 \\ \text{or} \quad & 100x_G + 96x_{p_2} + 66x_{n_2} + 52x_{p_3} + 49x_{n_3} + 48x_{p_4} \leq 192 \\ & x_G, x_{p_2}, x_{n_2}, x_{p_3}, x_{n_3}, x_{p_4} \geq 0, \text{ integer} \end{aligned}$$

Next, if  $s_n = 1/5+1/2\delta = 17/80$ , where  $\delta = 40$ . Then,  $LS(4) = \{1/2 + 1/2\varepsilon, (1-17/80)/2 + 1/2\varepsilon, 1/3 + 1/4\varepsilon, (1-17/80)/3 + 1/2\varepsilon, 1/4 + 1/8\varepsilon, 17/80\} = \{81/160, 65/160, 163/480, 66/240, 81/320, 17/80\}$ , where  $\varepsilon = 40$ . Then, the constraint becomes

$$486x_G + 390x_{p_2} + 326x_{n_2} + 264x_{p_3} + 243x_{n_3} + 204x_{p_4} \leq 960$$

### An integer program for $1/6 < s_n \leq 1/5$ , as the occupied space and sizes of items in Table 3.

First, if  $s_n = 1/5$ , then  $LS(5) = \{1/2+1/2\varepsilon, (1-1/5)/2+1/2\varepsilon, 1/3+1/4\varepsilon, (1-1/5)/3+1/2\varepsilon, 1/4+1/8\varepsilon, (1-1/5)/4+1/2\varepsilon, 1/5+1/16\varepsilon, 1/5\} = \{242/480, 194/480, 161/480, 130/480, 241/960, 98/480, 385/1920, 1/5\}$ , where  $\varepsilon = 120$ . The integer program is as follows:

$$\begin{aligned} \max \quad & \frac{4}{5}x_G + \frac{1}{2}x_{p_2} + \frac{2}{5}x_{n_2} + \frac{1}{3}x_{p_3} + \frac{4}{15}x_{n_3} + \frac{1}{4}x_{p_4} + \frac{1}{5}x_{n_4} + \frac{1}{5}x_{p_5} \\ \text{s.t.} \quad & \frac{242}{480}x_G + \frac{194}{480}x_{p_2} + \frac{161}{480}x_{n_2} + \frac{130}{480}x_{p_3} + \frac{241}{960}x_{n_3} + \frac{98}{480}x_{p_4} \\ & + \frac{385}{1920}x_{n_4} + \frac{1}{5}x_{p_5} \leq 1 \\ \text{or} \quad & 968x_G + 766x_{p_2} + 644x_{n_2} + 520x_{p_3} + 482x_{n_3} + 392x_{p_4} \\ & + 385x_{n_4} + 384x_{p_5} \leq 1920 \\ & x_G, x_{p_2}, x_{n_2}, x_{p_3}, x_{n_3}, x_{p_4}, x_{n_4}, x_{p_5} \geq 0, \text{ integer} \end{aligned}$$

Next, if  $s_n = 1/6+1/2\delta = 7/40$ , where  $\delta = 60$ . Then,  $LS(5) = \{1/2 + 1/2\varepsilon, (1-7/40)/2 + 1/2\varepsilon, 1/3 + 1/4\varepsilon, (1-7/40)/3 + 1/2\varepsilon, 1/4 + 1/8\varepsilon, (1-1/5)/4 + 1/2\varepsilon, 1/5 + 1/16\varepsilon, 7/40\}$ , where  $\varepsilon = 60$ . Then, the constraint becomes

$$488x_G + 404x_{p_2} + 324x_{n_2} + 272x_{p_3} + 242x_{n_3} + 206x_{p_4} + 193x_{n_4} + 168x_{p_5} \leq 960$$
