# Stereoselective Recognition of Amino Alcohols and Amino Acids by Carbonylurea- and Carbonyguanidinium-based Imine Receptors 

Raju Nandhakumar, Yun Soo Ahn, Hoe-Jin Yoon, and Kwan Mook Kim ${ }^{\times}$<br>Bio-Chiral Lab, Department of Chemistry and Nano Sciences, Ewha Womans Unwersity, Seoul 120-750, Korea<br>${ }^{*} E$-mail: kknookia ewha ac.kr<br>Received July 30, 2009, Accepted October 14, 2009

#### Abstract

New receptors 1-3 that bind stereoselectively amino alcohols and convert chirality of amino acidsvia imine bond formation were synthesized. The receptors have uryl (1), thiouryl (2) and guanidinium (3) groups all with additional phenylcarbonyl motifs, which are effective hy drogen bonding donors and play a key role in the stereoselective recognitions. The stereoselectivities were measured from the integration of ${ }^{1} \mathrm{HNMR}$ peaks. Compound $\mathbf{1}$ and $\mathbf{2}$ showed the stereoselectivities for the imine formation with amino alcohols $\left(K_{R} / K_{s}\right)$ in the range of $2 \sim 4$, and compound 3 in the range of $4 \sim 8$. Chirality conversion efficienciesof 1-3 for amino acids, i.e. D/L ratio at equilibrium, are in the range of $1.5 \sim 5.6$, showing a little higher efficiency with 3 . The additional phenylcarbonyl motifs in $\mathbf{1 - 3}$ were revealed not to contribute to significant enhancement of the selectivities.

Key Words: Stereoselective recognition. Imine receptor, Chirality conversion, Anino alcohol. Amino acid

Intmduction
Molecular recognition. especially chiral recognition. is one of the significant processes for diverse chemical and biological phenomena. The study of synthetic modeling systems for chiral recognition of amino alcohols. ${ }^{1}$ amino acids ${ }^{2}$ and amines ${ }^{3}$ is an area of ever increasing research activity. ${ }^{+}$Although much progress has been made, it remains a challenge to develop highly stereoselective receptors for these substrates based on simple organic molecules.

We have developed a simple organic receptor witha uryl pending group that enantioselectively binds an amino acid and converts L -amino acid to D -amino acid. ${ }^{56}$ The receptor binds the substrate via imine bond which is well known to be reversible. Resonance Assisted Hydrogen Bonding (RAHB) ${ }^{8}$ stabilizes the imine bond formed between the aldehyde of the receptor and amino group of the substrate. The uryl group in the receptor binds carbonylate group of the substrate by another hydrogen bonding. The complementarity and directionalityof those hydrogen bondings contribute substantially to the enantioselectivity. Hence we modified the uryl group to provide efficient hydrogen bonding. The modified receptors contain guanidinium. pyrrole, imidazolium and diuryl groups instead of the uryl group. which demonstrated high enantioselectivities for aminoalcohols and peptides besides amino acids. ${ }^{5-12}$ Furthermore these receptors are efficient chiral selectors that are useful inan extractive resolution process which is an industrially cost-effective and time-saving one. ${ }^{9.11 .13}$

In this context. we designed new receptors 1-3 based on uryl. thiouryl and guanidinium groups with additional pheny lcarbonyl motif (Scheme 1). The carbonyl group provides the additional hydrogen bonding acceptor site and modify the hydrogen bonding donor capability of the uryl or guanidinyl group by electronic effect. Here we report the synthesis and enantioselectivities of those receptors for amino alcohols and amino acids.

Scheme 1

## Results and Discussion

Compound 1 was sy nthesized according to Scheme 2 . Benzoyl isocyanate and 3 -aminobenzyl alcohol 4 were reacted in THF to form 3-benzoyluryl-benzyl alcohol 5 , which on further treatment with phosphorous tribromide gave 3-benzoylurylbenzyl bromide 6 . Addition of 6 to mono methoxymethyl (MOM) protected binol aldehyde $7^{\text {sa }}$ inDMF under the presence of sodium hy dride led to the formation of the MOM protected benzoyluryl-based binol 8 in $82 \%$ yield, which upon hydrolysis under acidic condition gave the optically pure benzoylurylbased binol receptor 1 in quantitative yield.

Unlike compound $\mathbf{1}$, compound 2 was synthesized following the procedures described in Scheme 3, because 3-benzoylthio-uryl-benzyl alcohol on treatment with $\mathrm{PBr}_{3}$ yields a mixture of compounds which decomposes so rapidly and cannot be isolated as pure form nor reacted directly with mono-MOMprotected binol aldehyde. The binol amine $9^{9}$ was reacted with benzoyl isothiocyanate in tetrahydrofuran to obtain the corresponding MOM-protected alcohol 10 in good y ield. The alcohol 10 was treated with pyridinium chlorochromate ( PCC ) in metlylene chloride and upon hydrolysis under acidic conditions gave the optically pure thiouryl-based binol receptor 2 . Compound 3 was synthesized starting from compound 10 as shown in Scheme 3. Treatment of compound 10 with mercuric chloride and liquor anmonia in ethanol yielded the guanidinium based com-

Scheme 2. Reagents and Conditions: (a) Benzoyl isocyanate, THF, rt , 5 h : (b) $\mathrm{PBr}, \mathrm{THF}, \mathrm{rt}, 2 \mathrm{~h}$ : (c) $\mathrm{NaH}, \mathrm{DMF}, \mathrm{rt}, 12 \mathrm{~h}$ : (d) conc. $\mathrm{HCl}, \mathrm{EtOH}$, retlux, 0.5 h .

Scheme 3. Reagents and Conditions: (a) THF, benzoylisothiocyanate, rt, 5 h ; (b) $\mathrm{PCC}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}, \mathrm{l}-5 \mathrm{~h}$; (c) conc. HCl , EtOH, reflus, 0.5 h : (d) mercuric chloride, liq. Ammonia, EtOH, rt, 2 h
pound 12. which on PCC oxidation and acid hydrolysis produced the final receptor 3 .

The final compounds 1-3 were confinmed by ${ }^{1} \mathrm{H} N M \mathrm{~N}$, ${ }^{13} \mathrm{C}$ NMR and HRMS, which are in good agreement with the presented stnictures. All the receptors are freely soluble in solvents such as DMSO. $\mathrm{CHCl}_{3}$ and benzene.

Figure 1 shows the stereoselective imine formation of the receptor $\mathbf{3}$ for 2 -aminopropanol (ap) as a representative. Figure la indicates the ${ }^{1} \mathrm{H}$ NMR spectrum for 3 in $\mathrm{CDCl}_{3}$. where the peak at 10.19 is due to - CHO and the doublet of doublet centered at 5.10 is due to the diastereotopic benzylic $\mathrm{CH}_{2}$. The addition of ( $S$ )-ap to the $\mathrm{CDCl}_{3}$ solution of 3 results in complete formation of the imine. 3-S-ap. within minutes. This can be clearly noted by the appearance of the imine proton peak at 8.68 ppm and the disappearance of the aldehyde peak (Fig. lb). Similarly. upon addition of $(R)$-ap, the imine proton peak of 3-R-ap appears at different position at 8.62 ppm (Fig. 1c). A noticeable discrimination between 3-S-ap and 3-R-ap is observed on diastereotopic benzylic - $\mathrm{CH}_{2}$ - signals: more prominent doublet of doublet splitting pattern for $3-\mathrm{R}-\mathrm{ap}$ centered at 5.15 ppm is observed. This implies that 3-R-ap is more rigid than 3-S-ap. i.e., stronger hydrogen bonding interaction is assumed for $3-R-a p$ between alcoholic - OH and guanidinium moiety. Figure ld shows the ${ }^{1} \mathrm{H}$

Figure 1. Partial 'H NMR spectra in $\mathrm{CDCl}_{3}$ of (a) 3, (b) 3-S-ap, (c) 3R -ap, and (d) misture of 3-S-ap and 3-R-ap formed by the addition of 2 equiv of racemic $a p$ to 3 .

NMR spectrum for a mixture of 3-R-ap and 3-S-ap formed by the addition of 2 equiv of racemic $a p$ to the $\mathrm{CDCl}_{2}$ solution of 3 . The ratio of 3-R-ap and 3-S-ap is conveniently obtained from

Table 1. The stercoselectivities ( $K_{\mathrm{R}} / K_{\text {; }}$ ) for the imine formation of roceptors 1-3

| Amines | $K_{\mathrm{k}} K_{;}$ |  |  |
| :--- | :---: | :---: | :---: |
|  | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ |
| methe lbeneslaminc | 1.00 | 1.00 | 1.00 |
| 2-amino-l-propanol | 3.31 | 2.25 | 6.25 |

| Phenylglycinol | 2.53 | 2.07 | 8.48 |
| Lencinol | 2.89 | 2.28 | 4.89 |

Figure 2. Fincrgy-minimized structure of 3-R-ap (a) and 3-S-ap (b) calculated by Molceular Mcchanics.
the signals of the sharp singlet imine peaks. Integration of the two peaks provides the ratio of 3-R-ap/3-S-ap as 2.5:1 at equilibrium. The same ratio has been obtained when either $(R)$-ap was added to 3-S-ap or ( $S$ )-ap was added to 3-R-ap. These indicate that the imine formation is a reversible thermodynamic process, and the imine formation constant for 3-R-ap $\left(K_{\mathrm{K}}\right)$ is larger than that for 3-S-ap $\left(K_{5}\right)$ by a factor of $2.5^{2}=6.25{ }^{14}$

We have compared the stereoselectivities ( $K_{1 /} / K_{\mathrm{S}}$ ) for the imine formation between receptors 1-3 and six representative aminoalcohols, 2-aminopropanol, 2-amino-1-butanol, 2-amino-3-methyl-1-butanol (valinol), 2-amino-3-phenyl-1-propanol (phenylalaninol), 2-amino-2-phenylethanol (phenylglycinol), and 2-amino-4-methyl-I-pentanol (leucinol) following the above mentioned protocol.

Table 1 lists the val ues of $K_{\mathrm{R}} / K_{\mathrm{s}}$ for six amino alcohols, which shows that the binol based receptors $\mathbf{1 - 3}$ bind all the amino alcohols with the same sense of stereoselectivity. The stercoselectivities of $\mathbf{1}$ and $\mathbf{2}$ are similar or slightly less than those of the previously reported uryl-based binol receptor. Those of $\mathbf{3}$ show higher values compared to $\mathbf{1}$ and $\mathbf{2}$, however, they are similar or slightly less than those of the previously reported guanidi-nium-based binol receptor. ${ }^{\text {. }}$ These guanidinium-based receptors have better selectivities due to the charge reinforced hydrogen bonding. ${ }^{9.11}$

Pigure 2 illustrates energy-minimized structure of imines 3-R-ap and 3-S-ap which are calculated by Molecular Mechanics with Spartan Program. ${ }^{15}$ Notable difference is the steric repulsion between imine proton and methyl group on $a p$. The repulsion of 3-R-ap is less than that of 3-S-ap, which is a key onigin of the stereoselectivity as proposed in our previous works.

Figure 3. Time-dependent ' H AMR of 3-L-Ala in DMSO-d $\boldsymbol{l}_{\text {in }}$ in the presence of 4 cquiy TE.A.

Table 2. L to D conversion efficiency of the receptors for amino acid

| Anmes | D / razio |  |  |
| :---: | :---: | :---: | :---: |
|  | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ |
| Ala | 2.51 | 1.80 | 3.32 |
| Ciln | 2.48 | 2.58 | 5.56 |
| Ilis | 2.90 | 1.82 | 3.85 |
| Phe | 1.53 | 3.12 | 3.45 |
| Ser | 1.96 | 2.32 | 4.77 |
| Tyr | 2.68 | 2.86 | 4.83 |

Benzoyl carbonyl group seems not to be involved in the hydrogen bonding with alcoholic OH group of ap . Thus the additional carbonyl group did not contribute to enhancement of the selectivity.

Furthermore, we have also studied the receptor activities for the conversion efficiency of amino acids from L -form to D form. In nature, L-amino acids are racemized by pyridoxal phosphate (PLP) dependent enzymes. ${ }^{1 / 1}$ The racemization is due to the acidification of $\alpha$ proton of the amino acid on the imine formed between the PLP and an amino acid. ${ }^{17}$ The receptors of this work form Schiff base like PLP, however, deracemize the bound amino acids unlike PLP due to the chirality of binol.

Partial ${ }^{1}$ II N.MR spectra in Figure 3 demonstrate the chirality conversion of $\mathbf{3}$-L-Ala (the imine formed between $\mathbf{3}$ and L-Alanine) to 3-D-Ala in the presence of triethylamine in DMSO- $d_{6}$. The imine CH signals are conveniently monitored as it is free from other signals. The singlet peak at 8.78 ppm assigned to the imine CH proton of 3-L-Ala decreases, and the singlet peak at 8.72 ppm ascribed to the imine ( H of $3-\mathrm{D}$-Ala increases concomitantly. Besides imine - CH peak, benzyl $-\mathrm{CH}_{2}$ - peaks centered at 5.12 for 3-L,Ala and 5.07 ppm for 3-I)-Ala, and alanine $\alpha$ proton peaks centered at 4.15 for 3 -L-Ala and 3.95 ppm for 3-D-Ala are also helpful to determine the chirality conversion. The intensities of the peaks reach the equilibrium at -

48 h . The stereoselectivity, which is defined by the ratio of (3-D-Ala)/(3-L-Ala), is measured by the integration of the corresponding signals.

Table 2 compares the stereoselectivities of the receptors 1-3 for representative six amino acids. alanine (Ala). Glutamine (Gln), histidine (His). phenyl alanine (Phe), serine (Ser) and tyrosine (Tyr). The stereoselectivities show a similar pattern with those of the amino alcohol case. While all the receptors show similar efficiencies. receptor $\mathbf{3}$ exhibits better efficiency. The selectivities are not satisfactory compared to those of our previously developed receptors.

## Conclusions

In summary. we have designed and synthesized receptors $\mathbf{1 - 3}$ with an additional carbonyl motif along with uryl, thiouryl and guanidinium moieties with the idea to enhance the hydrogen bonding thereby obtaining higher stereoselectivities in chiral recognition of amino alcohols and chirality conversion in amino acids. However, the additional carbonyl group is not helpful as expected in obtaining higher enantioselectivity in both amino alcohols and amino acids.

## Experimental Section

General. Compounds 7 and 9 were prepared according to the literature procedure. ${ }^{6.9}$ All other chemicals were commercially available and used without further purifications. The solvents for dry reactions were dried with appropriate desiccants and distilled prior to use. NMR spectra were recordedon a BrukerAM 250 spectrometer in $\mathrm{CDCl}_{3} \&$ DMSO- $d_{6}$ solutions containing tetramethylsilane as internal standard. Chemical shifts are reported in $\delta$ unit. Melting points were measured with Electrothermal IA 9000 digital melting point apparatus and are uncorrected. HRMS spectra were obtained on EI or FAB mode. For column Chromatographỵ silica gel of 230-400 mesh was used.

Compound 5: To a solution of 3-aminobenzyl alcohol ( 0.45 g . $3.74 \mathrm{mmol})$ in THF ( 30 mL ) , benzoy lisocyanate ( 0.50 g .3 .40 mmol) was added and stirred at ambient temperature for 5 h . Evaporation of the solvent and addition of chloroform gave a white precipitate, which is filtered and dried in vacuum to obtain 0.92 g of 5 .
