# Geographic Genetic Contour of A Leaf Beetle, Chrysolina aurichalcea (Coleoptera: Chysomelidae), on the Basis of Mitochondrial COI Gene and Nuclear ITS2 Sequences 

Joong Won Park, Sun Young Park, Ah Rha Wang, Min Jee Kim, Hae Chul Park ${ }^{\mathbf{1}}$, and Iksoo Kim*<br>Institute of Emvironmentally-Friendly Agliculture, College of Agriculture \& Life Sciences, Chonnam National University, Gwangju 500-757, Korea<br>${ }^{1}$ Department of Agricultural Biology, National Academy of Agricultural Science, Suwon 441-100, Republic of Korea

(Received 27 August 2011; Accepted 10 September 2011)

The leaf beetle, Chrysolina aurichalcea (Coleoptera: Chysomelidae), is a pest damaging plants of Compositae. In order to understand the genetic diversity and geographic variation we sequenced a portion of mitochondrial COI gene ( 658 bp ) and complete nuclear internal transcribed spacer 2 (ITS2) of the species collected from seven Korean localities. A total of 17 haplotypes (CACOI01~CACOI17), with the maximum sequence divergence of $3.04 \%$ ( 20 bp ) were obtained from COI gene sequence, whereas 16 sequence types (ITS2CA01~ITS2CA16), with the maximum sequence divergence of $2.013 \%(9 \mathrm{bp})$ were obtained from ITS2, indicating substantially larger sequence divergence in COI gene sequence. Phylogenetically, the COI gene provided two haplotype groups with a high nodal support ( $\geq 87 \%$ ), whereas ITS 2 provided only one sequence type group with a high nodal support ( $\geq \mathbf{9 2} \%$ ). The result of COI gene sequence may suggest the presence of historical biogeographic barriers that bolstered genetic subdivision in the species. Different grouping pattern between COI gene and ITS2 sequences were interpreted in terms of recent dispersal, reflected in the ITS2 sequence. Finding of unique haplotypes and sequence types only from Beakryeng-Islet population was interpreted as an intact remnant of ancient polymorphism. As more samples are analyzed using further hyper-variable marker, further fruitful inference on the geographic contour of the species might be available.

[^0]Key words: Mitochondrial DNA, COI gene, ITS2, Leaf beetle, Chrysolina aurichalcea, Ancestral polymorphism

## Introduction

The leaf beetle, Chrysolina aurichalcea (Coleoptera: Chysomelidae), damages young leaves of the species of Compositae and is a damaging pest along with the aphid, Cryptosiphum artemisiae, to the mugwort Artemisia species (Choo et al., 1992). The species damages most severely during May $\sim$ June, tends to damage in night, and have death feigning behavior (http://100.naver.com/ insect). The species is distributed in Korea, Japan, China, Taiwan, and eastern region of Russia including Sakhalin (Kimoto and Takizawa, 1994; Kim, 2001).
The species in Japan has been reported to have four different karyotypes, three of which are also present in Korea, although exact zoogeographic information for such diversification is unknown (Fujiyama, 1989). Subsequent study for Japanese populations has reported that $2 \mathrm{n}=31$ (male) and $2 \mathrm{n}=41$ (male) are two major karyotypes (Fujiyama and Okamoto, 1996), but have very few difference in external morphology, except for a slight difference in male reproductive organ (Fujiyama, 1989). Laboratory crossing experiment also supported reproductive isolation between the two types by both pre-mating and post-mating mechanisms (Fujiyama, 1989). In a subsequent study, the two types were found in the same microhabitats within sympatric zone, suggesting that postmating mechanism is more strong (Kitamura et al., 2010).

In contrast to the recognition of reproductive isolation sequence and phylogenetic analyses using mitochondrial NADH dehydrogenase subunit 2 (ND2) gene from an
extensive sample of the two karyotypes have shown cooccurrence of identical haplotypes in different types in several localities and non-monophyly in either of the two karyotypes (Kitamura et al., 2008). These results collectively were used to suggest that chromosomal changes
occurred rapidly and recently, possessing ancestral polymorphism in ND2 sequences (Kitamura et al., 2008).

Currently, studies on Korean populations of the $C$. aurichalcea is limited only to the status as pest and its host plant (Choo et al., 1992), whereas, no other genetic

[^1]and molecular perspective study has yet been performed. In order to expand our understanding about the species for a diverse purpose including pest control strategy an inference on genetic population structure may offer us important biological information by enabling us to understand about magnitude of genetic diversity and genetic relationships among localities (Roderick, 1996). In particular, it would be important to investigate whether or not populations of the species occurring in Korean peninsula also hold ancestral polymorphisms in mitochondrial DNA (mtDNA) and distribution of the polymorphism.

In the present study, therefore, we investigated the geographic genetic contour of C. aurichalcea using partial sequence of mitochondrial cytochrome $b$ oxidase subunit I (COI) gene and completely sequenced nuclear ribosomal internal transcribed spacer 2 (ITS2) in order to grab hold of population genetic information of the species. Previously, mitochondrial COI gene sequence has been utilized to illustrate several geographic genetic perspectives of insects occurring in the Korean peninsula (Jeong et al., 2009; Kim et al., 2009). Further, this region that is widely used as "DNA barcode region" (Hebert et al., 2003) has been suggested to provide early insight into the patterning of genomic diversity within species (Hajibabaei et al., 2007). The ITS2 that is located between 5.8S and 28 S rRNA genes is one of the fast evolving non-coding regions of the nuclear ribosomal DNA (Arnheim, 1983; Miller et al., 1996). Thus, this region has been investigated in a broad array of studies including population genetic studies (Fritz et al., 1994; Mukabayire et al., 1999; Marcilla et al., 2001; Wörheide et al., 2002) including insects occurring in Korean peninsula (Oh et al., 2009; Kang et al., 2011).

## Materials and Methods

## Insects

Adult Chrysolina aurichalcea were caught from seven Korean localities from June 2009 to May 2010. The samples were frozen at $-70^{\circ} \mathrm{C}$ until being used in molecular analysis. Sampling information on collection locality, number, and date are provided in Table 1, and the locality map is shown in Fig. 1. The different sampling sizes may reflect the difference in population size at each locality, considering that a similar effort for sample collection was made.

## Primer design

In order to amplify and sequence the COI gene we used the primer set COLCOIF1 ( 5 '- AAACTAWTARCCT-TCAAAG-3') and HCO2198 (5'- TAAACTTCAGGGT-

Fig. 1. Sampling location of chrysolina aurichalcea in Korea.

GACCAAAAATCA-3'). HCO2198 was adopted from Folmer et al. (1994), but COLCOIF1 was designed in this study from the alignment of tRNA ${ }^{\text {Trp }}$ and neighboring genes of mtDNA from several full-length mitochondrial genomes of Coleoptera. For the amplification of ITS2, primers NG02955 ( 5 '-ATGAACATCGACATTTCGAACG-CACAT-3') and AB052895 (5'-TTCTTTTCCTCCGCT-TAGTAATATGCTTAA-3') located on the 5.8 S and 28 S rDNAs, respectively, were successfully used ( Ji et al., 2003; Table 2).

## DNA extraction, PCR, cloning, and sequencing

From the frozen hind leg total DNA was extracted with a Wizard Genomic DNA Purification Kit using the manufacturer's instructions (Promega, USA). For the amplification of the $658-\mathrm{bp}$ region of COI gene, PCR was conducted under the following conditions: an initial denaturation step at $94^{\circ} \mathrm{C}$ for 7 min , a 35 -cycle amplification $\left(94^{\circ} \mathrm{C}\right.$ for $1 \mathrm{~min}, 47.8 \sim 56^{\circ} \mathrm{C}$ for 1 min , and $72^{\circ} \mathrm{C}$ for 1 min ), and the final extension step for 7 min at $72^{\circ} \mathrm{C}$. For PCR of ITS2, an initial denaturation step at $94^{\circ} \mathrm{C}$ for 7 min, a 35 -cycle amplification $\left(94^{\circ} \mathrm{C}\right.$ for $40 \mathrm{sec}, 55 \sim 60^{\circ} \mathrm{C}$ for 30 sec , and $72^{\circ} \mathrm{C}$ for 40 sec ), and the final extension step for 2 min at $72^{\circ} \mathrm{C}$ were conducted. Successfully amplified PCR products were subjected to DNA purification using PCR purification Kit (Bioneer, Korea). The COI gene amplicons were directly sequenced, whereas those from ITS2 were cloned into a pGEM-T Easy vector (Promega). For the cloning process, XL1-Blue competent

cells (Stratagene, USA) were transformed with the ligated DNA, and the resultant plasmid DNA was isolated using a Wizard Plus SV Minipreps DNA Purification System (Promega). DNA sequencing was conducted using the ABI PRISM ${ }^{\circledR}$ BigDye ${ }^{\circledR}$ Terminator ver. 3.1 Cycle Sequencing Kit with an ABI 3100 Genetic Analyzer (PE Applied Biosystems, USA). All products were sequenced from both strands.

## Sequence analysis and phylogenetic relationships

Bi-directionally sequenced individual sequences were aligned using MAFFT ver. 6 (Katoh et al., 2002). COI gene sequences were delimitated to the site just after each
primer site, resulting in 658 bp . Comparison of several $C$. aurichalcea sequences registered in Bold System (http:// www.barcodinglife.com/) turned out to be $98 \%$ sequence homology to one intraspecific sample (AY_796210). On the other hand, the boundary of the ITS2 sequence was delimited using the Hidden Markov Model-based ITS2 annotation software, with the model selection set to either Metazoa or Diptera and the maximum E-value set as the default value, E $<0.001$ (Keller et al., 2009). When the homologous sequences from two individuals differed by one or more nucleotide base (for both COI and ITS2) or one insertion/deletion (indel) position (for ITS2), the sequences were considered either different haplotypes (for COI) or sequence types (for ITS2). Haplotype or sequence type designations were applied to new sequences as they were discovered (i.e., CACOI01 and CACOI01 and so forth for COI, and ITS2CA01, ITS2CA02, ITS2CA03 and so on for ITS2).

Unlikely COI haplotypes ITS2 sequences contain indel positions, which make alignment inaccurate. Thus, the aligned sequences were subjected to GBlocks analysis (ver. 0.91 b ) in order to select conserved regions with the maximum number of contiguous non-conserved positions set to four (Castresana, 2000). Resultantly, 14 indel positions were reduced to seven positions and this equivalent to the sequence length from 515 positions reduced to 481 positions ( $93 \%$ of original positions). Further, subsequence sequence analysis was performed using "afterGBlocks sequence" in order to avoid uncertainty.

Phylogenetic analysis among the COI haplotypes and ITS2 sequence types was respectively conducted via the maximum-parsimony (MP) method (Fitch 1971) using Phylogenetic Analysis Using Parsimony and Other Method (PAUP) ver. 4.0b10 (Swofford, 2002). The reliability of the trees was assessed by 1,000 iterations of bootstrapping (Felsenstein, 1985). To root trees, the homologous region of a within-familial species, Crioceris duodecimpunctata for COI gene (Stewart and Beckenbach, 2003) (GenBank accession number AF467886) or within-generic species C. timarchoides for ITS2 (GomezZurita et al., 2000) was used as outgroup, respectively.

## Gene flow

The genetic distance was estimated from ITS2 data using Arlequin ver. 3.0 software (Excoffier et al., 2005). Population genetic distance between pairs of locality $\left(F_{\mathrm{ST}}\right)$ and its permutation test to obtain the statistical significance of the value ( 1,000 bootstraps) were determined in accordance with the approach described by Excoffier et al. (1992), with the selection of algorithm, Kimura' twoparameters method, to calculate the distance between DNA sequences (Kimura, 1980). Pairwise $N_{m}$ (the product
of the effective population size, $N_{e}$, and migration rate, $m$ ) values were used to estimate the pairwise $F_{\mathrm{ST}}$ based on the equilibrium relationship: $F_{\mathrm{ST}}=1 /\left(4 N_{m}+1\right)$.

## Results and Discussion

## Sequence analysis

A total of 17 COI haplotypes and 16 ITS2 sequence types (23 types before GBlocks analysis to select conserved blocks for ITS2) were obtained by sequencing 34 individuals of Chrysolina aurichalcea collected from seven localities in Korean peninsula (Table 1). Individual sequence information was deposited in the GenBank database (Table 1). Although COI gene revealed no indels, presenting all identical 658 bp , ITS2 was variable in length, ranging from 474 bp to 485 bp . Sequence alignment of COI gene revealed 35 variable nucleotides, 30 of which are transitions ( 13 TC and 17 GA ), 4 of which are transversions ( 3 AC and 1 TA ), and one of which is polymorphic site (TCA) (Table 2). Among them, five of nucleotide substitutions caused amino acid change. In the case of ITS2 a total of 26 variable sites were detected. This consisted of 16 sites of transitions ( 5 TC and 11 GA ), 4 sites of transversions ( 1 TG and 3 TA ), and 6 indels (Table 2).

Uncorrected pairwise comparison between pairs of haplotypes and sequence types is displayed in Tables 3 and 4, respectively. The sequence divergence among 17 haplotypes ranged from $0.152 \%$ to $3.04 \%$ ( $1 \sim 20 \mathrm{bp}$ ) and the highest estimate was found in a comparison between CACOI13 and CACOI15. On the other hand, uncorrected pairwise distance among 16 sequence types showed the maximum divergence of $1.699 \%$ ( 8 sites) and the highest estimate was found in a comparison between ITS2CA05 and ITS2CA06 (Table 4). This estimate for COI is quite high considering other relevant studies, which utilized homologous COI gene. For example, the estimate was $0.2 \%$ for the domestic silkworm (Kim et al., 2000), $0.2 \%$ and $1.2 \%$ for two species of mushroom flies (Bae et al., 2001), $0.3 \%$ for a bumblebee, Bombus ardens (Kim et al., 2009), $0.45 \%$ for the tiny dragonfly (Kim et al., 2007b), $0.76 \%$ for the mason bee (Kim et al., 2008), $0.9 \%$ for the diamondback moth (Li et al., 2006), $0.91 \%$ for the swallowtail butterfly (Jeong et al., 2009), $0.91 \%$ for a ground beetle, Scarites aterrimus (Wang et al., 2011), 1.67\% for the cabbage butterfly (Jeong et al., 2009), 4.0\% for the firefly, Luciola lateralis (Kim et al., 2001), 5.0\% for another firefly, Pyrocoelia rufa (Lee et al., 2003), and $11 \%$ for the oriental mole cricket (Kim et al., 2007a). The two firefly species and the mole cricket have been reported to have a taxonomic implication (Kim et al., 2001; Lee et al., 2003; Kim et al., 2007). Thus, excluding

these species, the maximum sequence divergence was roughly $\leq 1.0 \%$ within species.

On the other hand, the divergence of ITS2 is substantially smaller than that of COI. Generally, it is known that ITS2 is fast evolving regions, relatively free from structural and functional constrains (Tang et al., 1996; Navajas et al., 1998).

## Geographic genetic contour

Phylogenetic analysis was investigated to know evolutionary relationships among haplotypes and sequence types and to find out any discernable groups in connection with geographic affinity (Fig. 2 and 3). Seventeen COI haplotypes were largely unresolved, presenting multibranches with low bootstrap values, but two groups were recognizable (groups A and B). Group A that has $87 \%$ of nodal support is composed of two haplotypes (CACOI11 and CACOI13), which are two among five haplotypes found in locality 5 (Eocheong-Islet). Group B that has $94 \%$ nodal support is composed of three haplotypes

Fig. 2. Phylogenetic analysis among 17 COI haplotypes of Chrysolina aurchalcea. The tree was acquired via the MP method incorporated in the PAUP software (Swofford, 2002). Crioceris duodecimpunctata (Genbank accession number AF467886) was used as an outgroup in order to root tree. The numbers on (under) the branches represent bootstrap values of 1,000 replications. Parentheses indicate the locality name, from which the particular haplotype was obtained. Two groups with relatively high node supporting value ( $>87 \%$ ) were recognized.
(CACOI15, CACOI16, and CACOI17), which are all the haplotype members found in locality 7 (Beakryeng-Islet) (Fig. 2). In the case of ITS2 only one group (group A) composed of two sequence types (ITSCA05 and ITSCA10) was strongly supported ( $92 \%$ of nodal support; Fig. 3). Geographically, ITSCA05 was found in four localities such as locality 1 (Yeongwol), locality 2 (Kwanak-gu), locality 3 (Andong), and locality 4 (Kang-seo-gu), whereas ITSCA10 was found only in locality 4 (Table 5).

Finding of phylogenetically subdivided COI haplotypes suggest the presence of polymorphism and this, in turn, suggests that the species occurring in Korean peninsula experienced historical biogeographic barriers that bolstered genetic subdivision. This result may be consistent with the ND2-based phylogeny with an extensive Japanese sample of the two karyotypes: co-occurrence of identical haplotypes in different types in several localities and non-monophyly in either of the two karyotypes (Kitamura et al., 2008). Their reasoning for such polymorphism

Fig. 3. Phylogenetic analysis of 16 ITS2 sequence types of the Chrysolina aurichalcea. The tree was acquired via the MP method incorporated in the PAUP (Phylogenetic Analysis Using Parsimony and Other) ver. 4.0b10 software (Swofford, 2002). Chrysorina timarchoides (Genbank accession number AJ279788.1) was used as an outgroup in order to root tree. The numbers on the branches represent bootstrap values of 1,000 replications. Parentheses indicate the locality name, from which the particular sequence type was obtained. One group with relatively high node supporting value ( $>92 \%$ ) was recognized.

Numbers in parentheses indicate sample size at each population. Locality names are as follows: 1, Yeongwol; 2, Kwanak-gu; 3, Andong; 4, Kangseo-gu; 5, Eocheong-Islet; 6, Seogwipo; and 7, Beakryeng-Islet.
without consistency to karyotype data was a rapid and recent chromosomal change, possessing ancestral polymorphism in ND2 sequences (Kitamura et al., 2008). In order to further test such possibility, nevertheless, more sensitive molecular markers revealing co-dominant nature might be required. Collectively, if individuals or populations carrying different karyotypes are truly present in Korean peninsula, one possible scenario that fulfills the
present data would be re-hybridization of once isolated populations, which carries different karyotypes. Nevertheless, this interpretation may not fully explain the mechanism by which individuals with different karyotypes can reproduce.

In contrast to COI gene sequences, the ITS2 data do not concordant with COI result in that the individuals involved in the clustering in COI sequences (sample num-

bers CA1971, CA1975, CA3317, CA3318, CA3320) are not involved in the clustering in ITS2 (sample numbers CA3286, CA3289, CA3298, CA3299, and CA3308) (Table 1) and their localities never overlap between the two data sets (Table 5). One of the possible interpretations for this inconsistency might be recent dispersal, considering that several sequence types (four among 16) are simultaneously found in more than one locality (Table 5). In geographic perspective, in fact, most localities have one or more sequence types that are also found in other localities, except for locality 7 (Beakryeng-Islet). Under the interpretation that ITS2 sequence is one of the fast evolving non-coding regions in insects (Navajas et al., 1998) sharing of identical sequence types among localities might be interpreted as the result of gene flow. In fact, genetic distance ( $F_{\mathrm{ST}}$ ) between pairs of populations suggest no statistically significant genetic separation ( $p<$ 0.05 ) and migration rates ( Nm ) estimates show at least more than two individuals per generation (between localities 1 and 2) by ITS2 sequences (Table 6). Thus, the result of our determinations of gene flow can be surmised that the C. aurichalcea populations on the Korean peninsula are quite well connected to each other.

## Beakryeng-Islet population

Unlikely other populations Beakryeng-Islet population (locality 7) possesses unique haplotypes (CACOI15, CACOI16, and CACOI17) and sequence types (ITS2CA14, ITS2CA15, and ITS2CA16) that have never been found in other populations. Although small sample size and lack of clustering among the three sequence types in ITS2 phy-
logeny renders somewhat decisive conclusion impossible finding of unique haplotypes and sequence types from Beakryeng-Islet population imply that the population might be an intact remnant of ancient polymorphism. If this is the case, this location might be a plausible ground worth to search to find individuals with consistent haplotype and karyotype. This is particularly likely, because this locality is northwestern most one among our sampling localities. As more samples are analyzed using further hyper-variable marker, further detailed information on this largely unknown species will be possible.
