# COMPETITION INDICES OF STRONGLY CONNECTED DIGRAPHS

HAN HYUK CHO AND HWA KYUNG KIM

ABSTRACT. Cho and Kim [4] and Kim [6] introduced the concept of the competition index of a digraph. Cho and Kim [4] and Akelbek and Kirkland [1] also studied the upper bound of competition indices of primitive digraphs. In this paper, we study the upper bound of competition indices of strongly connected digraphs. We also study the relation between competition index and ordinary index for a symmetric strongly connected digraph.

### 1. Preliminaries and notations

Let D = (V, E) denote a *digraph* (directed graph) with vertex set V = V(D), arc set E = E(D). Loops are permitted but multiple arcs are not. A  $x \to y$  walk in a digraph D is a sequence of vertices  $x, v_1, \ldots, v_t, y \in V(D)$  and a sequence of arcs  $(x, v_1), (v_1, v_2), \ldots, (v_t, y) \in E(D)$ , where the vertices and arcs are not necessarily distinct. A *closed walk* is a  $x \to y$  walk where x = y. A *cycle* is a closed  $x \to y$  walk in which all vertices except x and y are distinct.

The length of a walk W is the number of arcs in W. The notation  $x \xrightarrow{k} y$  is used to indicate that there is a  $x \to y$  walk of length k. The distance from vertex x to vertex y in D, denoted by d(x, y), is the length of a shortest walk from x to y. An *l*-cycle is a cycle of length *l*, and is denoted by  $C_l$ . If the digraph D has at least one cycle, the length of a shortest cycle in D is called the girth of D, and is denoted by s(D).

A digraph D is called *strongly connected* if for each pair of vertices x and yin V(D) there is a walk from x to y. For a strongly connected digraph D, the *index of imprimitivity* of D is the greatest common divisor of the lengths of the cycles in D, and is denoted by k(D). If D is a trivial digraph of order 1, k(D)is undefined. For a strongly connected digraph D, D is *primitive* if k(D) = 1. If D is primitive, there exists some positive integer l such that there is a walk

of length exactly l from each vertex x to each vertex y. The smallest such l is called the *exponent* of D, denoted by  $\exp(D)$ . Exponents have been studied by many researchers [2, 7, 8, 9, 10].

Cho et al. [5] introduced the *m*-step competition graph, a generalization of the competition graph. Let D be a digraph (with or without loops) with the vertex set  $\{v_1, v_2, \ldots, v_n\}$ . Given a positive integer m, we say that a vertex  $v_k$ of D is an *m*-step common prey of  $v_i$  and  $v_j$  if there are two directed walks of length m, one from  $v_i$  to  $v_k$  and the other from  $v_j$  to  $v_k$ . Then, the *m*-step competition graph of D, denoted by  $C^m(D)$ , has the same vertex set as D, and there is an edge between vertices  $v_i$  and  $v_j$  ( $v_i \neq v_j$ ) if and only if  $v_i$  and  $v_j$ have an *m*-step common prey in D. The *m*-step digraph of D, denoted by  $D^m$ , has the same vertex set as D and an arc ( $v_i, v_j$ ) if and only if there is a directed walk of length m from  $v_i$  to  $v_j$ . Then we have  $C^m(D) = C(D^m)$  for each positive integer m, see [5].

Consider the sequence  $D, D^2, D^3, \ldots, D^m, \ldots$  Then there exists a smallest positive integer q such that  $D^q = D^{q+r}$  for some positive integer r. Such an integer q is called the *index* of D and is denoted by index(D). There also exists a smallest positive integer p such that  $D^q = D^{q+p}$ , and such an integer is called the *period* of D and is denoted by period(D). Now, consider the competition graph sequence  $C(D), C(D^2), C(D^3), \ldots, C(D^m), \ldots$  There exists a smallest positive integer q such that  $C(D^{q+i}) = C(D^{q+r+i})$  for some positive integer rand every nonnegative integer i. Such an integer q is called the *competition index* of D and is denoted by cindex(D). Let q = cindex(D). Then there exists a smallest positive integer p such that  $C(D^{q+i}) = C(D^{q+r+i})$  for every nonnegative integer i. Such an integer p is called the *competition index* of D and is denoted by cindex(D). Let q = cindex(D). Then there exists a smallest positive integer p such that  $C(D^{q+i}) = C(D^{q+p+i})$  for every nonnegative integer i. Such an integer p is called the *competition period* of Dand is denoted by cperiod(D). From the definition of index and competition index, we get the following.

**Proposition 1.1** (Cho and Kim [4]). For a digraph D, we have

 $\operatorname{cindex}(D) \leq \operatorname{index}(D).$ 

Note that for a primitive digraph D,  $\exp(D) = \operatorname{index}(D)$  and  $\operatorname{cindex}(D)$  is the smallest integer q such that  $C(D^k)$  is a complete graph for any  $k \ge q$ . It is well known that the index of imprimitivity of D is equal to  $\operatorname{period}(D)$  for a strongly connected digraph D (For details on exponent (index) and period, refer to [3, 5, 8, 9, 10]). However, the competition period of a strongly connected digraph is always one, as shown below;

**Proposition 1.2** (Cho and Kim [4]). For a strongly connected digraph D, we have

$$\operatorname{cperiod}(D) = 1.$$

*Proof.* Note that each vertex of D has an outgoing arc. Thus, every edge in  $C(D^m)$  is an edge in  $C(D^{m+i})$  for every positive integer i, since any two vertices having an m-step common prey also have an (m + i)-step common prey. Therefore, we have cperiod(D) = 1.

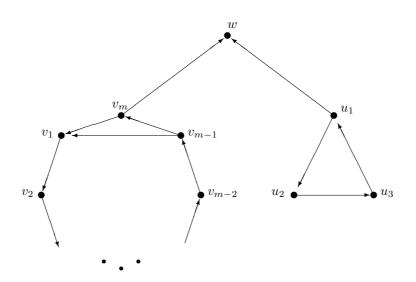

FIGURE 1.  $U_n$  where n = m + 4

Note that the competition period of a digraph may not be 1 when it is not strongly connected. For example, consider the above digraph  $U_n$ . Notice that there exist walks  $u_1 \xrightarrow{3k-2} w$ ,  $u_2 \xrightarrow{3k} w$  and  $u_3 \xrightarrow{3k-1} w$  for each positive integer k. Therefore we have the competition period of  $U_n$  is not 1, but 3.

In [4], the upper bound of competition indices of primitive digraphs were studied as follows.

Lemma 1.3 (Cho and Kim [4]). Let D be a primitive digraph D of order  $n (\geq 3)$  with girth s.

- (1) If n is odd, then  $\operatorname{cindex}(D) \le n + \left(\frac{n-3}{2}\right)s$ . (2) If n is even, then  $\operatorname{cindex}(D) \le n 1 + \left(\frac{n-2}{2}\right)s$ .

Akelbek and Kirkland [1] have introduced the scrambling index of a primitive digraph. Scrambling index is the smallest positive integer k such that for every pair of vertices u and v, there exists a vertex w such that  $u \xrightarrow{k} w$  and  $v \xrightarrow{k} w$  in D. Akelbek and Kirkland's definition of scrambling index is the same as our definition of the competition index in the case of primitive digraphs. In [1], they presented the following result regarding the scrambling index.

Lemma 1.4 (Akelbek and Kirkland [1]). Let D be a primitive digraph with n vertices and girth s.

- (1) If s is odd, then  $\operatorname{cindex}(D) \le n s + \left(\frac{s-1}{2}\right)n$ . (2) If s is even, then  $\operatorname{cindex}(D) \le n s + \left(\frac{n-1}{2}\right)s$ .

Lemma 1.4 gives a better upper bound for the competition indices of primitive digraphs than Lemma 1.3.

For each integer  $n(n \ge 3)$ , a Wielandt digraph of order n is a digraph isomorphic to  $W_n$ , as shown in below. Then  $W_n$  is a primitive digraph with girth n-1, and cindex $(W_n) = \omega_n$  where  $\omega_n = \left\lceil \frac{(n-1)^2+1}{2} \right\rceil$  for a positive integer n, [1, 4].

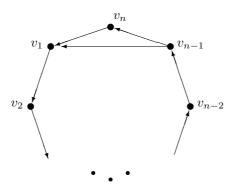

FIGURE 2. the Wielandt digraph  $W_n$ 

Akelbek and Kirkland [1] and Cho and Kim [4] have considered the upper bound of the competition index of a primitive digraph as follows.

**Theorem 1.5** (Akelbek and Kirkland [1], Cho and Kim [4]). Let D be a primitive digraph of order n. Then,

$$\operatorname{cindex}(D) \le \left\lceil \frac{(n-1)^2 + 1}{2} \right\rceil.$$

Equality holds if and only if D is a Wielandt digraph.

In Section 2, we consider the upper bound of the competition index of a strongly connected digraph. We also study the competition index of a symmetric digraph in Section 3.

#### 2. Competition indices of strongly connected digraphs

We consider competition indices of strongly connected digraphs. Suppose  $k = k(D) \ge 1$ . Then, there exists a vertex partition  $\{V_1, V_2, \ldots, V_k\}$  of the vertices V of D such that for each  $1 \le i \le k$ , every arc goes from  $V_i$  to  $V_{i+1}$  for some i, where  $V_{k+1} = V_1$ . Let  $E_i$  be the subgraph of  $D^k$  induced by  $V_i$ . Then,  $E_i$  is primitive (refer to Theorem 3.4.5 in [2]).

640

Consider the strongly connected digraph  $T_{11}$  shown in Figure 3. Note that  $k(T_{11}) = 2$ . Let  $V_1 = \{v_2, v_4, v_6, v_8, v_{10}\}$  be a set of black vertices and  $V_2 = \{v_1, v_3, v_5, v_7, v_9, v_{11}\}$  be a set of white vertices. Then,  $\{V_1, V_2\}$  forms a vertex partition of  $T_{11}$ .

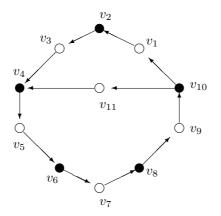

FIGURE 3. Digraph  $T_{11}$  with index of imprimitivity 2

Now, consider the induced subgraph  $E_1$  (respectively,  $E_2$ ) of  $V_1$  (respectively,  $V_2$ ) in the 2-step digraph  $T_{11}^2$  of  $T_{11}$  as shown in Figure 4. Then  $T_{11}^2$  is a disjoint union of  $E_1$  and  $E_2$ . Note that  $E_1$  is a Wielandt digraph of order 5. We also have cindex $(E_1) = 9$  and cindex $(E_2) = 10$ . Furthermore, we have cindex $(T_{11}) = 19$ .

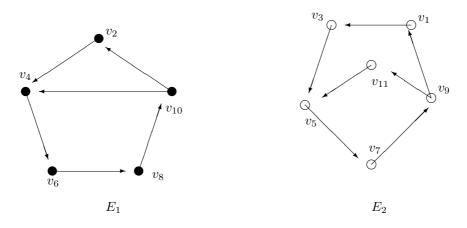

FIGURE 4. Its induced subgraphs  $E_1$ ,  $E_2$ 

Let D be a strongly connected digraph. For a pair of vertices u and v having a k-step common prey, let cindex(D : u, v) denote the smallest positive integer k such that u and v have a k-step common prey. If u and v do not have any k-step common prey, we let cindex(D : u, v) = 1. We also let cindex(D : u, u) = 1. Let cindex(D : u) denote max{cindex $(D : u, v)|v \in V(D)$ }. Then we have cindex $(D) = \max{cindex(D : u)|u \in V(D)}$  and cindex $(D) = \max{cindex(D : u, v)|u, v \in V(D)}$ .

Now, let D be a primitive digraph. For a pair of vertices u and v in V(D), let  $\exp(D: u, v)$  denote the smallest integer k such that there exists a directed walk of length t from u to v in D for all  $t \ge k$ , and let  $\exp(D: u) = \max\{\exp(D: u, v) | v \in V(D)\}$ . Then, we have  $\exp(D) = \max\{\exp(D: u, v) | u, v \in V(D)\}$ .

**Theorem 2.1.** Suppose k(D) = k for a strongly connected digraph D. Let  $V_1$ ,  $V_2, \ldots, V_k$  be k nonempty sets, with  $V_{k+1} = V_1$ , where each arc of D issues from  $V_i$  and enters  $V_{i+1}$  for some i with  $1 \le i \le k$ . Let  $E_i$  be the subgraph of  $D^k$  induced by  $V_i$ , where  $1 \le i \le k$ , and  $m = \min \{ \text{cindex}(E_i) \mid i = 1, 2, \ldots, k \}$  in  $D^k$ . Then, we have

$$\operatorname{cindex}(D) \leq k(m+1) - 1.$$

*Proof.* We show that  $\operatorname{cindex}(D:u,v) \leq k(m+1) - 1$  for any two vertices u and v. If  $u \in V_i$ ,  $v \in V_j$ , and  $i \neq j$ , then u and v do not have an l-step common prey for any positive integer l. Thus,  $\operatorname{cindex}(D:u,v) = 1$ . Suppose  $u, v \in V_j$  and  $m = \operatorname{cindex}(E_r)$  for some  $1 \leq j, r \leq k$ . Let u', v' be vertices in  $V_r$  such that there exist walks  $u \xrightarrow{f} u'$  and  $v \xrightarrow{f} v'$ , where  $0 \leq f \leq k - 1$ . Since  $\operatorname{cindex}(D^k:u',v') \leq \operatorname{cindex}(E_r)$ , we have

$$\begin{aligned} \operatorname{cindex}(D:u,v) &\leq f + \operatorname{cindex}(D:u',v') \\ &\leq k - 1 + k \cdot \operatorname{cindex}(D^k:u',v') \\ &\leq k - 1 + k \cdot \operatorname{cindex}(E_r). \end{aligned}$$

We have  $\operatorname{cindex}(D : u, v) \leq k(m + 1) - 1$ . Thus, we have  $\operatorname{cindex}(D) = \max{\operatorname{cindex}(D : u, v)|u, v \in V(D)} \leq k(m + 1) - 1$ . This establishes the result.

Note that the inequality in Theorem 2.1 is sharp. For the digraph  $D = T_{11}$  shown in Figure 3, we have that k = 2,  $m = 9 = \text{cindex}(E_1)$ , and  $\text{cindex}(T_{11} : v_1, v_5) = 19$ . Thus, we have  $\text{cindex}(T_{11}) = k(m+1) - 1$ .

**Lemma 2.2.** Let D be a strongly connected digraph of order  $n \geq 3$ . If  $k(D) > \frac{n}{2}$ , then we have

$$\operatorname{cindex}(D) \le \left\lfloor \frac{n-1}{2} \right\rfloor.$$

*Proof.* Let the girth of D be s. If  $k(D) > \frac{n}{2}$ , then every cycle in D has the same length s(=k(D)). Let  $V_1, V_2, \ldots, V_s$  be s nonempty sets, with  $V_{s+1} = V_1$ , where each arc of D issues from  $V_i$  and enters  $V_{i+1}$  for some i with  $1 \le i \le s$ .

643

Consider two vertices  $u \in V_i$  and  $y \in V_j$ . If  $i \neq j$ , or i = j and u = v, then cindex(D : u, v) = 1. If u and v do not have l-step common prey for any positive number l, then cindex(D : u, v) = 1. Without loss of generality, we may assume that cindex(D : u, v) = m > 1 and  $u, v \in V_s$ . Then we have walks such that  $u \rightarrow u_1 \rightarrow \cdots \rightarrow u_m = w$  and  $v \rightarrow v_1 \rightarrow \cdots \rightarrow v_m = w$ , where  $u_i \neq v_i$  and  $u_i, v_i \in V_i$   $(i = 1, \dots, m-1)$ . Therefore we have  $2m + 1 \leq n$  and cindex $(D : u, v) = m \leq \lfloor \frac{n-1}{2} \rfloor$ . This establishes the result.  $\Box$ 

From Theorem 2.1 and Lemma 2.2, we have the following theorem.

**Theorem 2.3.** Suppose D is a strongly connected digraph of order  $n \geq 3$ . Then, we have

cindex
$$(D) \le \omega_n = \left\lceil \frac{(n-1)^2 + 1}{2} \right\rceil$$
.

This equality holds if and only if D is isomorphic to  $W_n$ .

*Proof.* Let k(D) = k. If k = 1, the above equality holds by Theorem 1.5. If n = 3 and  $k \ge 2$ , we can check that  $\operatorname{cindex}(D) \le \omega_n$ . If  $k(D) > \frac{n}{2}$ , this equality holds by Lemma 2.2. Assume that  $2 \le k \le \frac{n}{2}$  and  $n \ge 4$ . Let  $V_1$ ,  $V_2, \ldots, V_k$  be k nonempty sets, with  $V_{k+1} = V_1$ , where each arc of D issues from  $V_i$  and enters  $V_{i+1}$  for some i with  $1 \le i \le k$ . Let  $E_i$  be the subgraph of  $D^k$  induced by  $V_i$ , where  $1 \le i \le k$ . Then, there exists a positive integer r such that the order of  $E_r$  is less than or equal to  $\lfloor \frac{n}{k} \rfloor$ . From Theorem 1.5, we have  $\operatorname{cindex}(E_i) \le \omega_{|V_i|}$  for each  $1 \le i \le k$  since each  $E_i$  is a primitive digraph. Therefore we have  $\operatorname{cindex}(E_r) \le \omega_{\lfloor \frac{n}{k} \rfloor}$ . By Theorem 2.1, we have

$$\begin{aligned} \operatorname{cindex}(D) &\leq k - 1 + k \cdot \operatorname{cindex}(E_r) \\ &\leq k - 1 + k \cdot \omega_{\lfloor \frac{n}{k} \rfloor} \\ &\leq k - 1 + k \cdot \frac{\left(\frac{n}{k}\right)^2 - 2\left(\frac{n}{k}\right) + 3}{2} \\ &= \frac{n^2}{2k} + \frac{5}{2}k - n - 1. \end{aligned}$$

Let  $g(k) = \frac{n^2}{2k} + \frac{5}{2}k - n - 1$   $(2 \le k \le \frac{n}{2})$ . Then g(k) attains the maximum value when k = 2.  $g(2) = \frac{n^2 - 4n + 16}{4} < \omega_n$  since  $n \ge 4$ . Therefore, we have cindex $(D) < \omega_n$  for a nonprimitive strongly connected digraph D. This establishes the result.

Next we study the competition indices of symmetric strongly connected digraphs.

## 3. Competition indices of symmetric strongly connected digraphs

In this section, we assume that D is a symmetric strongly connected digraph of order  $n (\geq 2)$ . Observe that in symmetric graphs, strongly connected is the same as connected. Since there is a 2-cycle in D, we have  $k(D) \leq 2$ . For a connected symmetric primitive digraph D, k(D) = 2 if D is bipartite, and otherwise k(D) = 1.

**Lemma 3.1** (Shao [8]). Let u and v be vertices of a symmetric primitive digraph D such that there exist directed walks of lengths  $k_1$  and  $k_2$ , respectively, with different parity between u and v. Then, we have

$$\exp(D: u, v) \le \max\{k_1, k_2\} - 1$$

**Proposition 3.2** (Shao [8]). Let  $E_n = \{\exp(D) : D \text{ is a symmetric primitive digraph of order } n \ge 4\}$ . Then we have

$$E_n = \{1, 2, \dots, 2n-2\} \backslash S,$$

where S is the set of all odd numbers in  $\{n, n+1, \ldots, 2n-3\}$ .

**Lemma 3.3.** Let D be a symmetric primitive digraph of order n. Then, for each vertex u, we have

$$\operatorname{cindex}(D:u) = \left\lceil \frac{\exp(D:u)}{2} \right\rceil.$$

*Proof.* Consider two vertices u and v in V(D).

First, we have two directed walks  $u \xrightarrow{\exp(D:u,v)} v$  and  $u \xrightarrow{\exp(D:u,v)+1} v$ . Since D is symmetric, u and v have a  $\left\lceil \frac{\exp(D:u,v)}{2} \right\rceil$ -step common prey. Therefore, we have

$$\operatorname{cindex}(D:u,v) \le \left| \frac{\exp(D:u,v)}{2} \right|.$$

Suppose u = v. Then there exists a vertex  $w \neq u$  such that  $u \xrightarrow{1} w$ , and there exists a directed walk  $u \xrightarrow{2 \cdot \operatorname{cindex}(D:u,w)} w$ . From Lemma 3.1, we have  $\exp(D:u,w) \leq 2 \cdot \operatorname{cindex}(D:u,w) - 1$ . Therefore, we have

 $\exp(D:u,v) \le \exp(D:u,w) + 1 \le 2 \cdot \operatorname{cindex}(D:u,w) \le 2 \cdot \operatorname{cindex}(D:u).$ 

Suppose  $u \neq v$ . If d(u, v) is odd, then we have two walks  $u \xrightarrow{d(u,v)} v$  and  $u \xrightarrow{2 \cdot \operatorname{cindex}(D:u,v)} v$ . From Lemma 3.1, we have  $\exp(D:u,v) \leq 2 \cdot \operatorname{cindex}(D:u) - 1$  since  $2 \cdot \operatorname{cindex}(D:u) > d(u,v)$ . If d(u,v) is even, then we have a vertex w such that  $u \xrightarrow{d(u,v)-1} w \ (\neq u) \rightarrow v$ . We also have  $u \xrightarrow{2 \cdot \operatorname{cindex}(D:u,w)} w$ . Since d(u,v) - 1 is odd, we have  $\exp(D:u,w) \leq 2 \cdot \operatorname{cindex}(D:u,w) - 1$ . Therefore,  $\exp(D:u,v) \leq \exp(D:u,w) + 1 \leq 2 \cdot \operatorname{cindex}(D:u,w) \leq 2 \cdot \operatorname{cindex}(D:u)$ . exp $(D:u,v) \leq 2 \cdot \operatorname{cindex}(D:u)$ . Therefore, we always have

$$\frac{\exp(D:u)}{2} \le \operatorname{cindex}(D:u).$$

From the above results, we have  $\frac{\exp(D:u)}{2} \leq \operatorname{cindex}(D:u) \leq \left\lceil \frac{\exp(D:u)}{2} \right\rceil$ . For each vertex u in D, we have

$$\operatorname{cindex}(D:u) = \left\lceil \frac{\exp(D:u)}{2} \right\rceil.$$

644

This establishes the result.

**Theorem 3.4.** If D is a symmetric strongly connected digraph, then we have

$$\operatorname{cindex}(D) = \left\lceil \frac{\operatorname{index}(D)}{2} \right\rceil$$

*Proof.* Let the order of D be n. If n = 1, this equality holds. Suppose  $n \ge 2$ . Then, we have  $k(D) \le 2$ .

Case 1. k(D) = 1

Note that  $index(D) = max\{exp(D:u)\}\)$  and  $cindex(D) = max\{cindex(D:u)\}\)$ . From Lemma 3.3, the result is established.

Case 2. k(D) = 2

There are bipartition  $V_1$  and  $V_2$  of the vertex set V(D). Consider two vertices  $u \in V_i$  and  $v \in V_j$ .

If  $i \neq j$ , we have  $\operatorname{cindex}(D:u,v) = 1$ . If i = j and  $\operatorname{index}(D)$  is even, there is a directed walk such that  $u \xrightarrow{\operatorname{index}(D)} v$ . Then, we have  $\operatorname{cindex}(D:u,v) \leq \frac{\operatorname{index}(D)}{2}$ . If i = j and  $\operatorname{index}(D)$  is odd, there is a directed walk such that  $u \xrightarrow{\operatorname{index}(D)+1} v$ . In all cases, we have  $\operatorname{cindex}(D:u,v) \leq \frac{\operatorname{index}(D)+1}{2}$ . Therefore, we have  $\operatorname{cindex}(D) \leq \left\lceil \frac{\operatorname{index}(D)}{2} \right\rceil$ . If i = j, there exists  $u \xrightarrow{2 \cdot \operatorname{cindex}(D)} v$ . If  $i \neq j$ , there is no  $u \xrightarrow{2 \cdot \operatorname{cindex}(D)} v$  and

If i = j, there exists  $u \xrightarrow{2 \cdot \operatorname{cindex}(D)} v$ . If  $i \neq j$ , there is no  $u \xrightarrow{2 \cdot \operatorname{cindex}(D)} v$  and there exist a vertex  $u' \in V_j$  and a directed walk such that  $u \xrightarrow{1} u' \xrightarrow{2 \cdot \operatorname{cindex}(D)} v$ . Then, we have  $D^{2 \cdot \operatorname{cindex}(D)} = D^{2 \cdot \operatorname{cindex}(D)+2}$ . Therefore, we have  $\operatorname{index}(D) \leq 2 \cdot \operatorname{cindex}(D)$ .

This establishes the result.

**Corollary 3.5.** If D is a symmetric primitive digraph of order  $n \ge 4$ , then  $\operatorname{cindex}(D) \le n-1$ , and equality holds if and only if D is a path with a loop on an end vertex.

*Proof.* From Proposition 3.2 and Theorem 3.4, we have  $\operatorname{cindex}(D) = \left\lceil \frac{\operatorname{index}(D)}{2} \right\rceil \le n-1$ . Since there are no symmetric primitive digraphs whose index is 2n-3 from Proposition 3.2, this corollary is proved.

## 4. Closing remark

In this paper, we have introduced the concept of the competition index of a digraph using the concept of the *m*-step competition graph introduced in [5]. For digraphs whose competition periods are one, there are some similarities between the property of the competition indices and that of ordinary indices or exponents. However, for digraphs whose competition periods are not one, there are significant differences between their competition indices and ordinary indices. In the case of the ordinary index, it is well known that  $index(D) \leq (n-2)^2 + 2$  for a reducible digraph D of order n, [7, 9]. This implies that the

645

index of a Wielandt digraph is the maximum possible index among indices of digraphs of order n. However, in the case of a competition index, the similarity between the properties does not hold. For example, consider the competition index of  $U_n$  shown in Figure 1. Then, we have  $\operatorname{cindex}(U_n) = m^2 - 2m + 3$  and  $\operatorname{cperiod}(U_n) = 3$ . Thus  $\operatorname{cindex}(U_n) > \omega_n$  when  $n \ge 15$ . That is, there is a reducible digraph of order n whose competition index is greater than that of any strongly connected digraph of order n. As shown in the example  $U_n$ , the competition indices of reducible digraphs are very interesting, and there is much work to be done.

Acknowledgement. We would like to thank an anonymous referee for his or her useful suggestions.
