Panax ginseng (PG) is a globally utilized medicinal herb. The medicinal effects of PG are primarily attributable to ginsenosides located in the root and leaf. The leaves of PG are known to be rich in various bioactive ginsenosides, and the therapeutic effects of ginseng extract and ginsenosides have been associated with immunomodulatory and anti-inflammatory activities. We examined the effect of PG leaf extract and the isolated ginsenosides, on nuclear factor (NF)- κ B transcriptional activity and target gene expression by applying a luciferase assay and reverse transcription polymerase chain reaction in tumor necrosis factor (TNF)- α -treated hepatocarcinoma HepG2 cells. Air-dried PG leaf extract inhibited TNF- α -induced NF- κ B transcription activity and NF- κ B-dependent cyclooxygenase (COX)-2 and inducible nitric oxide synthase (iNOS) gene expression more efficiently than the steamed extract. Of the 10 ginsenosides isolated from PG leaves, Rd and Km most significantly inhibited activity in a dose-dependent manner, with IC₅₀ values of 12.05 \pm 0.82 and 8.84 \pm 0.99 μ M, respectively. Furthermore, the ginsenosides Rd and Km inhibited the TNF- α -induced expression levels of the COX-2 and iNOS gene in HepG2 cells. Air-dried leaf extracts and their chemical components, ginsenoside Rd and Km, are involved in the suppression of TNF- α -induced NF- κ B activation and NF- κ B-dependent iNOS and COX-2 gene expression. Consequently, air-dried leaf extract from PG, and the purified ginsenosides, have therapeutic potential as anti-inflammatory.

INTRODUCTION

Although inflammation is a basic response to injury or infectious agents, the harmful effects of inflammation cause various chronic diseases including arthritis, fibrosis, and even cancer. Inflammatory responses play important roles during liver diseases in humans and animals. Hepatitis results from inflammation of the liver, characterized by inflammatory cells present in the organ tissue. Hepatitis can be acute (lasting less than 6 months) or chronic, when it persists longer. Chronic hepatitis is

associated with a high risk of liver cancer [1]. At the molecular level, free radicals and aldehydes produced during chronic hepatitis can induce deleterious gene mutations and posttranslational modifications in cancer-associated genes [2,3]. Other inflammatory products, including cytokines, growth factors, and transcription factors such as nuclear factor (NF)- κ B, control the expression of cancer genes (e.g., suppressor genes and oncogenes) and key inflammatory enzymes, such as inducible nitric oxide

synthase (iNOS) and cyclooxygenase (COX)-2 [4-7].

NF- κ B is known to play an important role in immune and inflammatory responses by regulating genes encoding pro-inflammatory cytokines, adhesion molecules, chemokines, growth factors, and inducible enzymes such as COX-2 and iNOS [8,9]. Therefore, NF- κ B signaling pathway inhibitors could be applied as novel anti-inflammatory compounds [10,11].

Panax ginseng (PG) Meyer (Araliaceae), a herbal drug applied in Oriental traditional medicine, has been used as a tonic for the treatment of various diseases [12-14]. Ginsenosides are the major active components of the PG. Despite the fact that PG root is considered the most valuable, the leaves contain the highest concentrations of ginsenosides [15-17]. Thus, ginseng leaves could function as a supplementary source of pharmacologically active ginsenosides [18,19].

Traditionally, PG root has been air-dried, yielding white ginseng, or steamed at 100°C to yield red ginseng. Steamed ginseng is believed to be more pharmacologically effective than air-dried ginseng. Differences in the biological effects of air-dried and steamed ginseng are attributed to significant ginsenoside changes during the steaming treatment [20]. However, the anti-inflammatory effects of air-dried and steamed leaves of PG have not been studied.

In our study, the MeOH extract of PG air-dried leaves significantly inhibited NF- κ B activity, with an IC₅₀ value of 39.12±2.79 μ g/mL. Here, we characterized the effects of 10 dammarane-type saponins from PG air-dried leaves on tumor necrosis factor (TNF)- α -induced NF- κ B activation, as well as iNOS and COX-2 gene expression, in HepG2 cells.

MATERIALS AND METHODS

Chemicals and sample preparation

In August 2008, PG leaves were collected in Geumsan, Korea, which is well-known for PG cultivation, and were taxonomically identified. A voucher specimen (CNU 08201) was deposited at the College of Pharmacy, Chungnam National University, Korea. PG air-dried leaves were extracted in MeOH (6.0 L \times 3, 50°C) and the combined extracts were lyophilized *in vacuo*. Ten ginsenosides, identified in our previous study, were isolated from PG air-dried leaves, i.e., ginsenosides F₁, Rb₁, Rb₂, Rc, Rd, Re, Rg₁, Ki, Km, and vinaginsenoside R₄ [16] (Fig. 1). To compare the anti-inflammatory activity of air-dried and steamed leaves, ginseng leaves were steamed at 120°C for 4 h under 0.15 MPa pressure, without mix-

ing, to yield the steamed-leaves sample, which was used for extraction. Pyrrolidine dithiocarbamate (PDTC), a NF- κ B inhibitor, was obtained from Sigma-Aldrich (St. Louis, MO, USA).

Cell lines and culture

HepG2 cells were maintained in Dulbecco's modified Eagle's medium (Invitrogen, Carlsbad, CA, USA) containing 10% heat-inactivated fetal bovine serum, 100 units/mL penicillin, and 10 μ g/mL streptomycin at 37°C and 5% CO₂. Human TNF- α was purchased from ATgen (Seoul, Korea).

Luciferase assay

Cells were seeded at 1 \times 10⁵ cells per well in a 12-well plate and grown for 24 h. All cells were transfected using lipofectamine LTX (Invitrogen), as described by the manufacturer. Luciferase activity was assayed using an LB 953 Autolumat (EG&G Berthold, Nashua, NH, USA), as described previously [21] and was normalized based on the expression of RSV- β -galactosidase. β -galactosidase activity was assayed colorimetrically. NF- κ B-Luc and iNOS-Luc plasmid were kindly provided by Dr. Kyoong E. Kim (Chungnam National University, Daejeon, Korea).

Cytotoxicity assay

An MTS assay (Promega Celltiter 96-Aqueous One Solution Assay; Promega, Madison, WI, USA) was used to analyze the effects of the compounds on cell viability. Cells were cultured overnight in a 96-well plate (\sim 1 \times 10⁴ cells/well). Cell viability was assessed after adding the compounds at 10 μ M for 24 h. The number of viable cells was determined by the A_{490nm} of the dissolved formazan product, after addition of MTS for 30 min, as described by the manufacturer (Promega).

Reverse transcription polymerase chain reaction

Total RNA was extracted with Easy-blue reagent (iNtRON Biotechnology, Seoul, Korea). Approximately 2 μ g of total RNA was reverse-transcribed using moloney murine leukemia virus reverse transcriptase and oligo-dT primers (Promega) for 1 h at 42°C. Polymerase chain reaction (PCR) of synthetic cDNA was performed using Taq polymerase pre-mixture (Takara, Shiga, Japan). PCR products were subjected to electrophoresis on 1% agarose gels, and stained with EtBr. PCR was conducted with the following primer pairs: iNOS sense 5'-TCATCCGCTATGCTGGCTAC-3', iNOS antisense 5'-CTCAGGGTCACGGCCATTG-3', COX-2 sense 5'-GCCAGCACTTCACGCATCAG-3', COX-2 an-

Fig. 1. Chemical structures of the ginsenosides Rd and Km.

tisense 5'-GACCAGGCACCAGACCAAAGACC-3', GAPDH sense 5'-TGTTGCCATCAATGACCCCTT-3', and GAPDH antisense 5'-CTCCACGACGTACT-CAGCG-3'. Quantification of PCR products was performed using the Quantity One Program (Bio-Rad, Hercules, CA, USA).

Statistical analysis

All results are expressed as the mean±SEM. Data was analyzed by one-factor ANOVA. Upon observation of a statistically significant effect, the Newman-Keuls test was performed to determine the difference between the groups. A *p*-value of less than 0.05 was considered to be significant.

RESULTS

Nuclear factor-κB inhibitory effect of *Panax ginseng* leaf extract in HepG2 cells

To evaluate and compare the anti-inflammatory activity of ginseng leaves, the nuclear transcription NF-κB cell-reporter system was applied. The anti-inflammatory activities of air-dried and steamed leaf MeOH extracts were measured using a luciferase assay in HepG2 cells. Extracts of air-dried leaves reduced NF-κB activation by 81% at 100 μg/mL and 43% at 10 μg/mL in a dose-dependent manner. Alternatively the steamed leaf extracts reduced NF-κB activation by 20% at 100 μg/mL (Fig. 2). This suggests that air-dried leaf extracts possess more anti-inflammatory effects than steamed leaves by inhibiting NF-κB in HepG2 cells.

Fig. 2. Effect of air-dried (ADL) and steamed (SL) *Panax ginseng* leaves on tumor necrosis factor (TNF)-α stimulated nuclear factor (NF)-κB transcriptional activity. HepG2 cells transiently transfected with pNF-κB-Luc were pretreated for 1 h with either vehicle (dimethyl sulfoxide) or extracts, then exposed to TNF-α (10 ng/mL) for 1 h. Unstimulated HepG2 cells acted as a negative control. Cells were then harvested and assayed for luciferase activity. Results are expressed as the mean luciferase activity±SEM (*n*=3). PDTC, pyrrolidine dithiocarbamate. *Significantly different from TNF-α stimulated group (*p*<0.05).

Effect of *Panax ginseng* leaf extracts on inducible nitric oxide synthase and cyclooxygenase-2 gene expression in HepG2 cells

To evaluate the anti-inflammatory activity of ginseng leaves which inhibited NF-κB activation in the luciferase assay, the effects of air-dried leaves and steamed leaf extracts on NF-κB target gene expression were evaluated by reverse transcription (RT)-PCR and iNOS promoter luciferase assay. HepG2 cells treated with TNF-α (10 ng/mL) had significantly upregulated iNOS and COX-2 mRNA expression (Fig. 3A) and iNOS promoter regulation (Fig. 3B). Air-dried leaf extracts significantly decreased iNOS and COX-2 mRNA and iNOS promoter activity compared to TNF-α-treated HepG2 cells (Fig. 3). Alternatively the steamed leaf extracts did not significantly inhibit gene expression (Fig. 3A). Therefore, air-dried leaves showed potent anti-inflammatory activity by inhibiting NF-κB activation and iNOS and COX-2 gene expression.

Effect of ginsenosides Rd and Km on inducible nitric oxide synthase and cyclooxygenase-2 gene expression through the nuclear factor-κB pathway

To identify novel NF-κB inhibitors from PG air-dried leaf extracts, 10 dammarane-type ginsenosides were evaluated using the luciferase assay and RT-PCR. Initially, to determine nontoxic concentrations, HepG2 cells were treated with various concentrations (0.1, 1, and 10 μM) of the compounds and cell viability was measured

Fig. 3. Effect of air-dried (ADL) and steamed (SL) *Panax ginseng* leaves on inducible nitric oxide synthase (iNOS) and cyclooxygenase (COX)-2 gene expression in HepG2 cell lines. (A) HepG2 cells were pretreated with extract or vehicle (dimethyl sulfoxide, DMSO) for 1 h, then exposed to tumor necrosis factor (TNF)- α (10 ng/mL) for 6 h. Total mRNA was extracted from the cell pellets using Easy-Blue reagent. The relative mRNA levels were assessed by reverse transcription polymerase chain reaction. Expression levels are displayed as the ratio of iNOS and COX-2 signal strength to a reference gene (GAPDH) to compensate for varying concentrations of RNA. (B) HepG2 cells transiently transfected with piNOS-Luc were pretreated for 1 h with either vehicle (DMSO) or extracts, then exposed to TNF- α (10 ng/mL) for 1 h. Unstimulated HepG2 cells acted as a negative control. Cells were then harvested and assayed for luciferase activity. Results are expressed as the mean luciferase activity \pm SEM ($n=3$). using an MTS assay. No compounds were significantly cytotoxic at up to 10 μ M, indicating that NF- κ B inhibition was not due to cell toxicity (Fig. 4A). HepG2 cells were pretreated with various ginsenosides at concentrations ranging from 0.1 to 10 μ M for 1 h and then induced with TNF- α for 20 h. Of these ginsenosides, Rd and Km significantly inhibited TNF- α -induced NF- κ B transcriptional activity with IC_{50} values of 12.05 \pm 0.82 and 8.84 \pm 0.99 μ M, respectively (Table 1 and Fig. 4B), while ginsenosides Rb₁, Rg₁, and F₁ reduced NF- κ B

Fig. 4. Effects of 10 ginsenosides on cell viability and nuclear factor (NF)- κ B transcriptional activity. (A) Cell viability was determined using the Promega Celltiter 96-Aqueous One Solution Assay. The results are expressed in terms of percentage relative cell viability. All values are means \pm SEM ($n=3$) vs. control. (B) Effect of Rd and Km on tumor necrosis factor (TNF)- α stimulated NF- κ B transcriptional activity. HepG2 cells transiently transfected with pNF- κ B-Luc were pretreated for 1 h with either vehicle (dimethyl sulfoxide, DMSO) or compounds, then treated with TNF- α (10 ng/mL). Unstimulated HepG2 cells acted as a negative control. Cells were harvested and assayed for luciferase activity. Results are expressed as the mean luciferase activity \pm SEM ($n=3$). transcriptional activity with IC_{50} values of 27.45 \pm 3.69, 28.14 \pm 0.28, and 22.36 \pm 2.20 μ M, respectively. Ginsenoside Rb₂ and vinaginsenoside R₄ weakly inhibited NF- κ B transcriptional activity (Table 1). Furthermore, ginsenosides Rc, Re, and Ki had no effects (Table 1). PDTC, as a positive control, potently inhibited NF- κ B transcriptional activity with an IC_{50} value of 3.35 \pm 0.61 μ M. Ginsenoside Rd and Km also inhibited expression of COX-2 and iNOS mRNA (Fig. 5A) and iNOS promoter activity in a dose-dependent manner (Fig. 5B). Therefore, ginsenoside Rd and Km showed potent anti-inflammatory activity by inhibiting NF- κ B activation and iNOS and COX-2 gene expression.

Table 1. Inhibitory activity (IC₅₀) of 10 ginsenosides isolated from air-dried leaves of PG on TNF- α induced NF- κ B activation in HepG2 cells

Compound	IC ₅₀ (μ M) ¹⁾
Ginsenoside F ₁	22.36 \pm 2.20

²⁾Positive control.

DISCUSSION

This study demonstrated that PG air-dried leaf extract, and its components, Rd and Km, inhibit TNF- α -induced NF- κ B promoter activity in HepG2 cells in a dose-dependent manner by interfering with gene transcription. Air-dried leaf extract, Rd and Km also inhibited the expression of two inducible enzymes, COX-2 and iNOS, at the transcriptional level, as demonstrated by reduced mRNA levels in TNF- α -treated HepG2 cells. Ginsenoside Rd was recently reported to suppress the inflammatory response by inhibiting expression of iNOS and COX-2 in rats, unexplained the regulatory mechanism [22]. In our study, we report the NF- κ B pathway, as a potential mechanism, by ginsenoside Rd in inflammation. To our knowledge, we are the first to report that air-dried leaf extracts and ginsenoside Km have an inhibitory effect on TNF- α -induced NF- κ B activation as well as iNOS and COX-2 expression in HepG2 cells.

Ginseng extracts and ginsenosides were previously shown to inhibit the NF- κ B pathway [23]. Saponins and *n*-butanol extracts of *P. notoginseng* (PNG) also inhibit the NF- κ B pathway in zymosan A- and collagen-induced mice [24]. Flower extracts from PNG attenuate the infarct volume in rat ischemic brain and the inflammatory response of microglia cells [25]. Also, the PG acid polysaccharide extract, ginsan, inhibits the production of interleukin (IL)-1 β , IL-6, IL-12, IL-18, and interferon- γ and the activation of MAPK, c-Jun N-terminal kinase,

Fig. 5. Effect of ginsenoside Rd and Km on inducible nitric oxide synthase (iNOS) and cyclooxygenase (COX)-2 gene expression in HepG2 cell lines. (A) HepG2 cells were pretreated with the ginsenosides Rd and Km, or the vehicle (dimethyl sulfoxide, DMSO) for 1 h, then treated with tumor necrosis factor (TNF)- α (10 ng/mL) for 6 h. Total mRNA was extracted from the cell pellets using Easy-Blue reagent. Relative mRNA levels were assessed by reverse transcription polymerase chain reaction. Expression levels are displayed as the ratio of iNOS and COX-2 signal strength to a reference gene (GAPDH), compensating for variations in the RNA concentrations. (B) HepG2 cells transiently transfected with piNOS-Luc were pretreated for 1 h with either vehicle (DMSO) or compounds, then treated with TNF- α (10 ng/mL). Unstimulated HepG2 cells acted as a negative control. Cells were harvested and assayed for luciferase activity. Results are expressed as the mean luciferase activity \pm SEM (*n*=3). and NF- κ B pathways in *Staphylococcus aureus*-infected mice [26,27]. However, the NF- κ B inhibitory effect of PG leaf extracts had not been evaluated.

In this study, ginsenosides Rb₁, Rg₁, and F₁ reduced NF- κ B transcriptional activity and ginsenoside Rb₂ and vinaginsenoside R₄ showed very low inhibitory activities (Table 1). Furthermore, ginsenosides Rc, Re, and Ki had no effects. In corroboration of our results, a study reported that ginsenoside Rb₁ inhibits the expression vascular cell adhesion molecule (VCAM)-1 by inhibiting the TNF- α -induced NF- κ B pathway in human umbilical vein endothelial cells [28]. Also, ginsenoside Rg₁ inhibits

iNOS production in mice injected with LPS and VCAM-1 as well as ICAM-1 production in ECV304 human endothelial cells induced by TNF- α [29]. Rb₂ potently inhibited TNF- α production in LPS-induced N9 microglia [30]. Vinaginsenoside R₄, identified from *P. vietnamensis* [31], had not previously been characterized. Ginsenoside F₁ protects human HaCat keratinocytes from ultraviolet-B-induced apoptosis [32]. However, the anti-inflammatory and NF- κ B inhibitory effects of ginsenoside F₁ had not been described. This is the first report of vinaginsenoside R₄ and ginsenoside F₁ inhibiting TNF- α -induced NF- κ B activation as well as iNOS and COX-2 gene expression in HepG2 cells. Although vinaginsenoside R₄ and ginsenoside F₁ may play the potential anti-inflammatory compound, further studies are necessary to determine the precise mechanism on TNF- α -mediated NF- κ B activation and inflammation.

In conclusion, we demonstrated that air-dried leaf extracts and their chemical components, ginsenoside Rd and Km, are involved in the suppression of TNF- α -induced NF- κ B activation; this was shown in a gene reporter assay by a reduction in luciferase activity, which subsequently inhibited iNOS and COX-2 gene expression. Our data demonstrated that air-dried leaf extract from PG and the purified ginsenosides, have therapeutic potential as anti-inflammatory, anti-atherosclerotic, anti-arthritis, anti-oxidative and antiallergic substances. However, detailed mechanisms of TNF- α -induced NF- κ B pathway inhibition and subsequent decreases in iNOS and COX-2 gene expression with air-dried leaf extracts from PG and ginsenosides require further investigation.
