**Abstract :** The study of pigs as a human disease model has been conducted in neuroscience. But the morphological development of pig brain by using MRI is rare. The purpose of this study is to determine whether cerebellum maintains consistent proportion to other brain regions in aging. Clinically healthy sixteen micropigs, 1, 2, 4, and 8 months were studied. The micropigs were anesthetized with isoflurane. MRI was acquired using a 0.3T system. To figure out development of ratio that allowed identification of normal cerebellum size, we measured the area of the cerebellum, brainstem, and forebrain from the mid-sagittal brain images on T1W. Mid-sagittal cross-sectional area (CSA) of total brain, forebrain, brainstem, and cerebellum were expressed as absolute values and also as percentages which were compared between the four age groups of micropigs for the purpose to define the effect of age on brain morphometry. It was found that there was not a significant difference in the percentage of the brain occupied by an individual region between groups although the absolute CSA differed significantly among age groups. There was no effect of age on the ratio between the cerebellum and total brain in 4 age groups. The normal size of cerebellum changes during brain development maintained a consistent ratio to other brain regions in normal micropigs. The ratio of CSA quantified on the mid-sagittal MR images offers a suitable method to detect presence of cerebellar anomalies in micropigs.

**Key words :** cerebellum, maturation, micropig, MRI

### Introduction

The micropig has been used as an experimental animal model in the field of neuroscience [13]. Morphologically, compared to other small laboratory animals, the pigs' brain resembles the human brain (gyrencephalic) more in anatomy, growth and development [6]. The studies of pig's brain with MRI are not sufficient, but the body composition analysis, MRI protocol for *in vivo* visualization, myelination study, microstructural and cerebrovascular changes are revealed [3, 8, 12, 19]. But the brain regions according to brain development using MRI are not studied.

The aim of this experiment is to describe the effect of age on brain morphometry (cerebellum, brainstem and forebrain) with mid-sagittal brain images using MRI.

### Materials and Methods

#### Animal preparation

Clinically healthy sixteen micropigs (1, 2, 4 and 8 month-age groups, Medi Kinetics micropigs; Medi Kinetics, Korea) were used for the brain morphometry. Each age group consists of 4 micropigs without gender difference, weighing from 5 to 20 kg.

All animals were raised under microbiologically well controlled conditions and dry food was provided with water *ad libitum*. This research strictly followed the guide line of the 'Guide for the Care and Use of Laboratory Animals' of Seoul National University, Korea.

#### Methods

All micropigs were anesthetized with propofol and isoflurane, and MRI scan was performed using a 0.3 T

magnet. On sagittal plane, T1 and T2-weighted images were acquired.

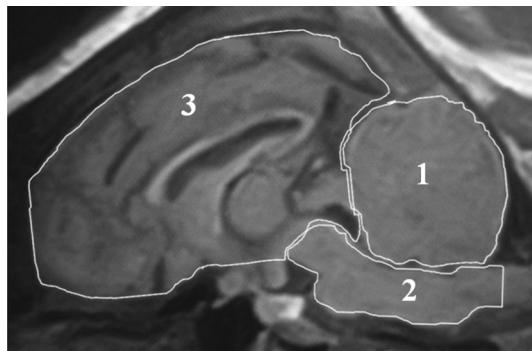

For image analysis, T1 weighted images on mid-sagittal cross-sectional area (CSA) of three brain regions were used for calculation of the cerebellum, brainstem and forebrain (Fig. 1). The outlines of the areas of three brain regions were manually traced. Mid-sagittal cross-sectional area (CSA) of total brain, forebrain, brainstem, and cerebellum were expressed as absolute values ( $\text{mm}^2$ ) and also as percentages to the total brain.

SPSS was used for data analysis. *P* values of below 0.05 were considered significant.

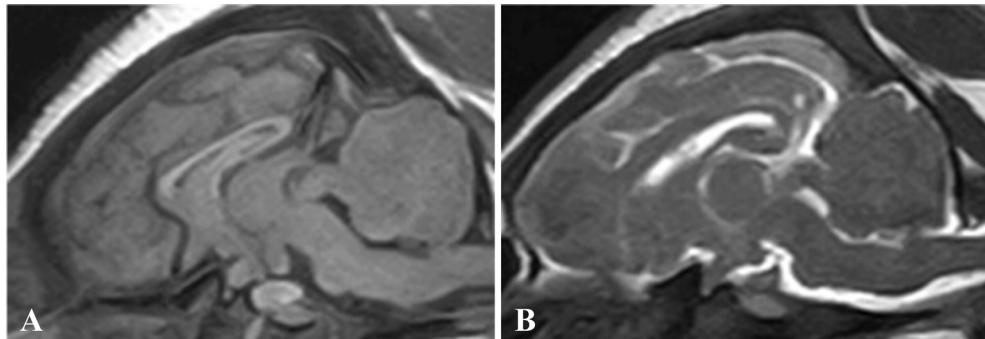

## Results

Mid-sagittal cross-sectional images of three brain regions were acquired (Fig. 1). We selected T1 weighted image for evaluating brain size, because the brain margin is more distinct so that it is easy to trace each brain region (Fig. 2). Mid-sagittal CSA of total brain, forebrain, brainstem, cerebellum, and ratio of the three brains to

total brain for groups in 1~8 month age range were calculated (Table 1). It is easy to recognize that as age increases, the area of the three brain regions also increase. To know the correlation between each three region to total brain, data distribution was established

**Fig. 1.** T1-weighted mid-sagittal MR image of the brain of a micropig. Note the manually traced outline of the three brain regions of interest: cerebellum (1), brainstem (2), forebrain (3).

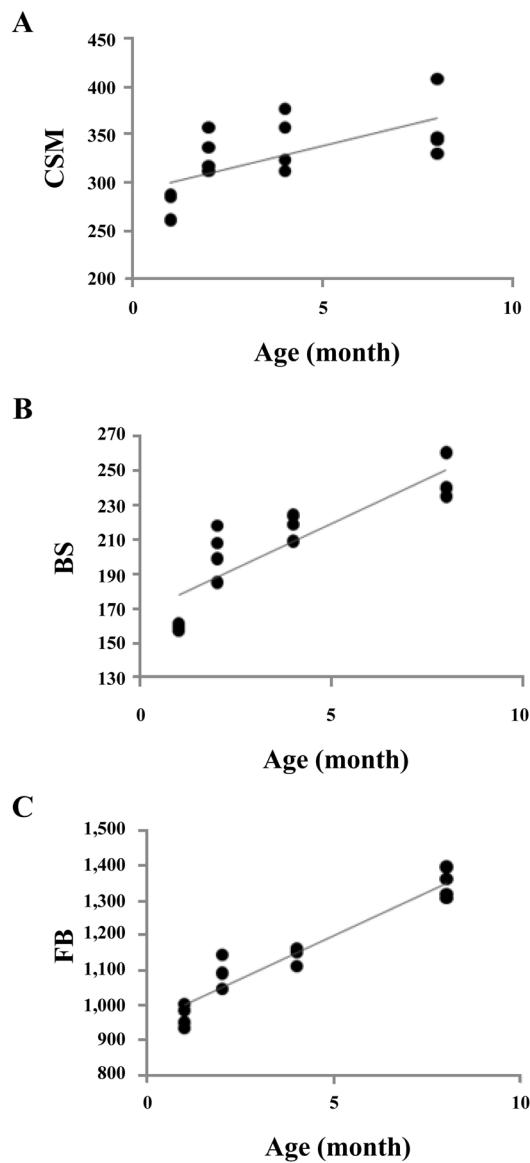

**Fig. 2.** Mid-sagittal CSA image of 2 month micropig. Images were scanned on the T1 weighted sequence (A), and on the T2 weighted sequence (B). Note that the brain margin on T1-weighted image is more distinct than on T2-weighted image.

**Table 1.** Mean and Standard Deviation of the Mid-sagittal cross-sectional area (CSA) of total brain, forebrain, brainstem, cerebellum, and ratio of the three brains to TB for groups in 1~8 month age range

	1 month	2 month	3 month	4 month
Total brain	$1,402.35 \pm 6.84$	$1,676.80 \pm 4.19$	$1,707.59 \pm 5.85$	$1,947.68 \pm 6.64$
Forebrain	$969.28 \pm 4.74$	$1,094.65 \pm 4.83$	$1,145.85 \pm 5.03$	$1,346.17 \pm 6.96$
Brainstem	$159.43 \pm 2.62$	$202.47 \pm 4.07$	$219.02 \pm 4.20$	$243.88 \pm 2.38$
Cerebellum	$273.64 \pm 4.27$	$331.26 \pm 2.73$	$342.67 \pm 2.61$	$357.62 \pm 2.83$
FB : TB (%)	$69.11 \pm 0.94$	$65.28 \pm 1.00$	$67.10 \pm 1.38$	$69.11 \pm 1.00$
BS : TB (%)	$11.36 \pm 0.29$	$12.07 \pm 0.56$	$12.82 \pm 0.40$	$12.52 \pm 0.29$
CBM : TB (%)	$18.33 \pm 0.84$	$19.75 \pm 0.60$	$20.67 \pm 1.33$	$18.33 \pm 0.91$

CSA:  $\text{mm}^2$ . FB: forebrain, TB: total brain, BS: brainstem, CBM: cerebellum. All data are expressed as the mean  $\pm$  SD (range).

**Fig. 3.** Relationship between cross-sectional area (CSA) of the cerebellum (A), brainstem (B), forebrain (C) with age. CSM: cerebellum; BS: brainstem; FB: forebrain. (A)  $R^2 = 0.4282$ ,  $p = 0.006$ ; (B)  $R^2 = 0.7625$ ,  $p < 0.0001$ ; (C)  $R^2 = 0.9161$ ,  $p < 0.0001$ .

using linear regression. There was a strong positive correlation between cross-sectional area of each brain region and age. Although the absolute CSA differed significantly among age groups, there was not a significant difference in the percentage of the brain occupied by an individual region between groups. There was no significant effect of age and weight on the CSA

**Fig. 4.** Relationship between CSA of the ratio of cerebellum to total brain with age and weight. CSM: cerebellum; TB: total brain. (A)  $R^2 = 0.2418$ ,  $p = 0.053$ ; (B)  $R^2 = 0.0198$ ,  $p = 0.084$ .

of the ratio of cerebellum to total brain in the four age groups when evaluated using linear regression (Fig. 4).

## Discussion

The cerebellum plays an important role in motor control and contributes to coordination, precision and accurate timing. When there is a lesion in the cerebellum, ataxia or incoordination of the head, neck and all four limbs with preservation of strength is usually caused [9]. In young animal, cerebellar abiotrophy, degeneration, hypoplasia, cortical atrophy and other diseases are reported in many species [2, 4, 5, 14, 15, 17, 18].

Though the cerebellum is thought to be one part of the brain, the MRI study of the pig with growth development and age is rare. In human studies, the cerebellum shows reduction in the volume of the cerebellar hemispheres and the cerebellar vermis with age advanced [7, 10, 11]. In one study of cerebellum volume of normal Koreans who were in their 20s and 40s, the volume of the cerebellum was significantly

larger in their 20s than those in their 40s and the volume significantly different according to gender and age, and the reduction of the volume of the cerebellum with age was significantly larger in men than in women [1], in another study, the time course and regional differences in age-related volume loss in cerebellum and brainstem, the volume remained stable until age 50 years and declined thereafter. Volume loss in the cerebellar vermis was striking [7].

In a study of the development of a morphometric MRI in the dog's brain, the ratio of the cerebellum to total brain and of the brainstem to cerebellum mid-sagittal cross-sectional area was compared. In this study, the percentage of the brain occupied by the cerebellum in diverse dog breeds between 1 and 5 years of age was not significantly different and cerebellum size did not change with increasing age [16].

In our study with micropigs, it was found that there was not a significant difference in the percentage of the brain occupied by an individual region between 1-month to 9-month age although the absolute CSA differed significantly among in different ages. And there was no effect of age on the ratio between the cerebellum and total brain in 4 age groups (18.3~20.7%). These results show similar trend like those in dogs (14.5~16.3%) [16]. The normal size of cerebellum change during brain development maintains a consistent ratio to other brain regions in normal micropigs, which is also a similar pattern like those in the dog and human.

But there are some limitation in our study with a narrow range of age group, lack of animal number and postmortem study. So, further study is needed for brain atrophy and degeneration in aged micropigs for human brain research.

MR imaging provide for the brain morphological and neuroanatomical information, and it is also a noninvasive imaging technique to assess morphometric analysis of CSA of the three brain regions. This measurement may be useful in the future for studying consistent ratio of cerebellum to total brain associated with age. This measurement that detects cerebellar abnormality would be very useful clinically.

In conclusion, while the size of the brain was directly related to the age and size of the animal, the cerebellum maintained a consistent ratio to other brain regions in normal micropig.

## Acknowledgments

This study was supported by a grant (2007 0401034006) from the Biogreen 21 program, Rural Development Administration, Korea.
