#### Abstract

A new synthetic route to N -Cbz-cis- $(3 R, 4 R)$-3-methylamino-4-methylpiperidine, key intermediate for CP690,550 , was disclosed with L-malic acid as the chiral pool starting material. The title compound was obtained in 16 steps with a total yield of $26 \%$ and more than $98 \%$ ee.

Key Words : $N$-Cbz-cis-(3R,4R)-3-methylamino-4-methylpiperidine, CP-690,550, L-Malic acid, Chiral pool

## Introduction

CP-690,550 (structure was shown in Figure 1), is developed by Pfizer and its discovery has been recently reported. ${ }^{1}$ It is a potent first-in-class Janas tyrosine kinase (JAK) inhibitor for treatment of autoimmune disease and organ transplant rejection, while its enantiomer is less powerful (as shown in Figure 1). ${ }^{1}$ Recent researches on the medicinal mechanism have revealed the potentially wide applications of this structural unit. ${ }^{2-11}$ Thus, convenient synthetic route to CP690,550 is demanded. In the view of retrosynthesis analysis of CP-690,550, disconnection at the methylamino group resulted in two fragments: cis-3-methylamino-4-methylpiperidine derivative (fragment A) and 4-chloro-7H-pyrrolo[2,3$d$ ]pyrimidine (fragment B) (Scheme 1). The synthesis of fragment B was divulged in our previous publication, ${ }^{12}$ and by others. ${ }^{13-17}$ To complete the total synthesis, fragment A is needed. We have reported a reasonable precursor for the synthesis of fragment A, $N$-Boc protected cis-3-methylamino-4-methylpiperidine. ${ }^{18}$ Recently, other synthetic routes to N protected cis-3-methylamino-4-methylpiperidine have also been reported. ${ }^{19-21}$ However, all these methods suffered from unusual materials, ${ }^{19-21}$ expensive catalysts, ${ }^{18}$ reagents ${ }^{18-21}$ and low yields. Thus, a new route with more accessible materials, high yield and most importantly, high ee, is required. In this paper, we disclose a new synthetic route to N -Cbz protected cis-( $3 R, 4 R$ )-3-methylamino-4-methylpiperidine (title compound) starting from L-malic acid with a total yield of $26 \%$ and ee of $>98 \%$.

## Experimental

General. All the reagents were chemical or analytical grade and were purified before use with standard procedure. Optical rotations were measured with a Perkin-Elmer 341 polarimeter in a 1 dm cell. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Varian AM- 400 MHz spectrometer using $\mathrm{CDCl}_{3}$ or DMSO- $d_{6}$ as the solvent and tetramethylsilane (TMS) as the internal standard. Chemical shifts ( $\delta$ ) were expressed in ppm downfield from internal TMS, and $J$ values were given in Hz. LC-MS spectra were obtained using an Agilent Technologies 6120MSD mass spectrometer. HRMS were performed on a Waters Q-TOF spectrometer. Thin layer chromatography (TLC) analyses were accomplished on silica gel 60 F254 plates. Chromatographic purification was performed on silica gel (200-300 mesh).
(S)-Dimethyl 2-Hydroxysuccinate (2). Thionyl chloride $(117 \mathrm{~g}, 0.98 \mathrm{~mol})$ was added to the solution of $\mathrm{L}-\mathrm{malic}$ acid $(59.9 \mathrm{~g}, 0.45 \mathrm{~mol})$ in methanol $(400 \mathrm{~mL})$ in ice-water bath. The resulting reaction mixture was stirred overnight at room temperature ( $\mathrm{rt}, 25^{\circ} \mathrm{C}$ ) after the completion of the addition. The reaction was monitored with TLC (EtOAc: $\mathrm{MeOH}=$ 10:1). The solvent was removed in vacuo. Saturated $\mathrm{NaHCO}_{3}$ solution ( 200 mL ) was added, and the aqueous phase extracted with EtOAc ( $3 \times 150 \mathrm{~mL}$ ). The combined organic phases were washed successively with water ( $3 \times 80 \mathrm{~mL}$ ), brine $(3 \times 80 \mathrm{~mL})$ and dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and the solvent was removed under reduced pressure. The ester 2 was isolated as light yellow oil in $98 \%$ yield ( $71.5 \mathrm{~g}, 0.44 \mathrm{~mol}$ ). $[\alpha]_{\mathrm{D}}^{20}=+8.9\left(\mathrm{EtOH}\right.$, c 1.20 , lit. ${ }^{53}[\alpha]_{\mathrm{D}}^{20}=+8.6, \mathrm{EtOH}, \mathrm{c}$

## Results and Discussion

The retrosynthesic concept is depicted in Scheme 2. It was envisaged that the fragment $\mathbf{A}$ could be prepared from an $N$ Cbz cis-(3R,4R)-3-methylamino-4-methylpiperidine (17), whereas 17 can be obtained from nitro compound 4 by reduction and a successive sequence of reactions. Compound 4 in turn could be formed from ester 3 by reduction and Henry reaction. Ester $\mathbf{3}$ is accessible from L-malic acid by successive esterification and methylation. Enantiomerically pure L-malic acid is commercially available.

Our synthesis is shown in Schemes 3, 5 and 6, and started from the successive esterification and $\alpha$-methylation of $\mathrm{L}-$ malic acid (Compound $\mathbf{1}$ ) to afford ester $\mathbf{3}$, by following the literature procedures with few modifications. ${ }^{22-26}$ Ester 3 was obtained in high yield (95\%), de ( $>20: 1$ ) and ee ( $>98 \%$ ) according to ${ }^{1} \mathrm{H}$ NMR spectrum. More importantly, the two stereocenters in ester $\mathbf{3}$ (trans) could be readily converted to cis by $\mathrm{S}_{\mathrm{N}} 2$ substitution with $\mathrm{NaN}_{3}$ (see below). The base used in the $\alpha$-methylation of methyl L-malic acid was lithium hexamethyldisilazide (LiHMDS), in lieu of lithium

diisopropylamide (LDA) for shorter reaction time and easier operation. Attention must be paid to the work-up of the $\alpha$ methylation of methyl L-malic acid. Water cannot be used to quench the reaction because LiOH , a strong base, could be formed, which led to the saponification of ester 3. Thus, a lower yield was obtained. Our experiments demonstrated that saturated aqueous $\mathrm{NH}_{4} \mathrm{Cl}$ was a good option and gave high yield.
The chemical environment differences between the two ester carbonyl groups make the selective reduction possible. Our experiments showed that with borane methyl sulfide (BMS)- $\mathrm{NaBH}_{4}$, the chemoselective reduction of ester 3 could be achieved and gave the diol 4 in good yield, according to the literature precedents. ${ }^{27-31}$ The reason for the chemoselectivity was discussed by Moriwake et al. ${ }^{54}$ The best ratio for BMS: $\mathrm{NaBH}_{4}$ :ester 3 was 1:0.1:1. Excess BMS could lead to over-reduction and thus lower yield was obtained. To obtain the key nitro compound 8, a Henry reaction is required, which means an aldehyde group has to be installed. As a result, the diol $\mathbf{4}$ had to be protected. Usually, reagents used for the protection of the adjacent diol are acetone and $p$ methyloxyphenyl aldehyde (PMP). However, the protection of diol $\mathbf{4}$ with either acetone or PMP was failed because the lactone was formed in acidic conditions (as seen in Scheme 4). While the diol 4 was stable at basic conditions, tertbutyldimethylsilyl (TBS) was chosen to be the proper protective group for further reactions. The protection was done under the standard conditions.

Aldehyde 6 was obtained from the reduction of ester 5 with DIBAL-H in excellent yield according to the literature procedure. ${ }^{28,32,33}$ Over-reduction could be restrained by using 1.0-1.15 equivalent DIBAL-H employed and shorter reaction time ( 30 min ). Moreover, the over-reduction product could be oxidized to aldehyde 6 with Dess-Martin reagent at rt in quantitative yield. Henry reaction of aldehyde 6 with

nitromethane under basic condition could afford nitro alcohol $7,{ }^{34-37}$ which was a mixture of two diastereomers. There was no need for further separation of the diasteromers because both of them could be transformed into nitro compound $\mathbf{8}$ through successive reaction with MsCl and $\mathrm{NaBH}_{4} .{ }^{38,39}$

Chemoselective deprotection of nitro compound $\mathbf{8}$ with HF-pyridine at rt furnished alcohol 9 in high yield, ${ }^{40,41}$ substitution of which with MsCl at rt provided compound $\mathbf{1 0}$. Cbz protected piperidine 11 was obtained from the subsequent reduction of the nitro group with $\mathrm{H}_{2} /$ Raney Ni , intramolecular cyclization and substitution reaction with benzyl chloroformate. The one-pot operation made the route concise. These reactions are carried out under ordinary conditions and high to excellent yields were obtained.

The deprotection of piperidine $\mathbf{1 1}$ with TBAF at rt offered the hydroxy piperidine $12,{ }^{42-44}$ substitution of which with MsCl at rt produced pyperidine $\mathbf{1 3}$, which was initially to undergo a $\mathrm{S}_{\mathrm{N}} 2$ reaction with aliphatic amine such as methylamine and benzylamine to form the final product. However, the conversion of piperidine $\mathbf{1 3}$ with the aliphatic amines was no more than $10 \%$ in solvents such as THF, DMF, dioxane, EtOH and MeOH , presumably due to the low nucleophilicity of the amine and severe steric hindrance.
To overcome this, the piperidine $\mathbf{1 3}$ was transformed to azide compound, which underwent Staudinger reduction to form amino piperidine compound $14 .{ }^{45-47}$ The direct methylation of amino piperidine compound $\mathbf{1 4}$ was not achievable
for the reasons described before. ${ }^{18}$ Reactions of amino piperidine $\mathbf{1 4}$ with $p$-anisaldehyde and formaldehyde under reductive conditions in DCM gave compound 16. ${ }^{48-50}$ Final product 17 was ultimately obtained upon removal of $p$ methoxybenzyl with CAN. ${ }^{51,52}$ Thus, the installation of methyl was achieved.

## Conclusion

In summary, we disclosed a new synthetic route to N -Cbz-cis-(3R,4R)-3-methyl-amino-4-methylpiperidine starting from L-malic acid in 16 steps. The final product was obtained in $26 \%$ total yield and $>98 \%$ ee. The route benefited from cheap raw materials, mild reaction conditions and easy operation. CP-690,550 should be readily accessible from title compound with reported procedure. ${ }^{1}$
