# NF-κB Activation and PPAR Transactivational Effects of a New Aliphatic Acid Amide from Pericarps of *Zanthoxylum piperitum*

Seo Young Yang,<sup>†</sup> Bui Huu Tai,<sup>†,‡</sup> Seok Bean Song,<sup>†</sup> Wei Li,<sup>†</sup> Xi Tao Yan,<sup>†</sup> Ya Nan Sun,<sup>†</sup> Nguyen Phuong Thao,<sup>†,‡</sup> and Young Ho Kim<sup>†,\*</sup>

<sup>†</sup>College of Pharmacy, Chungnam National University, Daejeon 305-764, Korea. <sup>\*</sup>E-mail: yhk@cnu.ac.kr <sup>‡</sup>Institute of Marine Biochemistry, Vietnam Academy of Science and Technology, 18 Hoang Quoc Viet, Caugiay, Hanoi, Vietnam Received January 27, 2014, Accepted April 18, 2014

A new aliphatic acid amide, ZP-amide F (1), and eight known compounds, including bungeanumamide A (2), tumuramide C (3), ZP-amide A (4), ZP-amide B (5), ZP-amide D (6), hyperin (7), quercitrin (8), and (–)-sesamin (9), were isolated from pericarps of *Zanthoxylum piperitum*. The effects of these compounds on TNF $\alpha$ -induced NF- $\kappa$ B activation and transactivational activity of PPARs, including PPAR $\alpha$ , PPAR $\beta(\delta)$  and PPAR $\gamma$  subtypes, were evaluated. Compounds 7 and 9 exhibited potent inhibitory effects on TNF $\alpha$ -induced NF- $\kappa$ B activation with IC<sub>50</sub> values of 5.50 and 8.10  $\mu$ M, respectively. Aliphatic acid amide compounds 3, 4 and 6 displayed enhanced effects on PPAR transactivational activity with EC<sub>50</sub> values of 47.12, 19.13 and 12.02  $\mu$ M, respectively. Among them, compound 4 demonstrated an increase in PPAR $\alpha$  transactivational activity, compound 3 showed a moderate increase on all PPAR subtypes, whereas compound 6 displayed weak PPAR transactivational activity.

Key Words : ZP-amide F, Zanthoxylum piperitum, Anti-inflammation, NF-KB, PPAR

### Introduction

Nuclear factor kappa B (NF-KB) is a transcription factor involved in the regulation of several important processes, such as cell proliferation, apoptosis, the immune response, and the inflammatory response.<sup>1-3</sup> Its main functions as a regulator in the immune response, inflammation, cell proliferation and survival have been well-established.<sup>4</sup> NF-KB regulates the expression of a wide variety of genes in the immune response, adhesion molecules, and pro-inflammatory cytokines in inflammatory cells. Activation of NF-κB by various stimuli, including inflammatory cytokines such as tumor necrosis factor alpha (TNF $\alpha$ ) and interleukin-1 (IL-1), T-cell activation signals, growth factors, and stress inducers, causes transcription at  $\kappa B$  sites that is associated with a number of diseases, such as inflammatory disorders and cancer.5,6 Therefore, inhibition of the NF-kB signaling pathway is a potent target for the prevention and/or treatment of cancers and inflammatory diseases.

Ligand-activated transcription factors belonging to the peroxisome proliferator-activated receptor (PPAR) family have recently been of much interest due to their possible regulatory role in the inflammatory and immune responses.<sup>7,8</sup> Their mode of action is indicated *via* formation of heterodimers with the nuclear receptor RXR, followed by binding to specific DNA-response elements in target genes known as peroxisome proliferator response elements (PPREs).<sup>9</sup> To date, three types of PPARs, including PPAR $\alpha$ , PPAR $\beta(\delta)$  and PPAR $\gamma$ , have been identified. PPAR $\alpha$  is expressed predominantly in liver, heart, kidney, intestinal mucosa, and brown adipose tissue (tissues with high catabolic rates for fatty acids and peroxisome metabolism).<sup>10,11</sup> PPAR $\beta(\delta)$  has become a pharmacological target for the treatment of metabolic disorders associated with metabolic syndromes, including dyslipidemia, obesity and insulin resistance.<sup>12</sup> PPAR $\gamma$  is the molecular target for insulin-sensitizing thiazolidinedione drugs such as troglitazone, pioglitazone and rosiglitazone, which have been approved for use in the treatment of type 2 diabetes.<sup>13,14</sup> Both PPAR $\alpha$  and PPAR $\gamma$  have been reportedly implicated in the regulation of macrophage and endothelial cell inflammatory responses.<sup>7</sup> Discovery of PPAR agonists has become a target for the prevention and treatment of obesity, insulin resistance, metabolic syndromes, inflammation, and cardiovascular disease.<sup>15</sup>

Zanthoxylum piperitum DC. (Rutaceae) is commonly known as Japanese pepper. It is a deciduous aromatic spiny shrub widely distributed in Eastern Asian countries, including China, Japan and Korea. In several folk medicine remedies, Z. piperitum is used for treatment of helminth infections and digestive organs. Fresh young leaves and dried fruits of Z. piperitum have been used as a pungent spice and bitter seasoning.<sup>16-18</sup> Phytochemical investigation of this plant has led to the isolation of terpenoids,<sup>17,19</sup> aliphatic acid amides,<sup>16,20</sup> alkaloids, phenolics, flavonoids, and lignans.<sup>21-23</sup> These compounds have reportedly shown various pharmacological effects, including antibacterial, anti-oxidant, anti-inflammatory, and repellent activities.<sup>24-27</sup> The present study describes the isolation and structural elucidation of a new aliphatic acid amide from a methanol extract of the pericarps of Z. piperitum. The effects of isolated compounds on transcriptional activity of TNFa-induced NF-kB and PPARs, including PPAR $\alpha$ , PPAR $\beta(\delta)$  PPAR $\gamma$  subtypes, were evaluat2362 Bull. Korean Chem. Soc. 2014, Vol. 35, No. 8

ed in HepG2 cells.

## **Results and Discussion**

A methanol extract (496.0 g) of *Z. piperitum* was suspended in water and successively partitioned with *n*-hexane, CH<sub>2</sub>Cl<sub>2</sub>, EtOAc, and *n*-BuOH. These fractions were subjected to various separation procedures, and nine compounds were isolated (Figure 1). Structures of known compounds (2–9) were elucidated by comparing spectroscopic data to published values, and identified as bungeanumamide A (2),<sup>28</sup> timuramide C (3),<sup>29</sup> ZP-amide A (4),<sup>16</sup> ZP-amide B (5),<sup>16</sup> ZP-amide D (6),<sup>16</sup> hyperin (7),<sup>30</sup> quercitrin (8),<sup>31</sup> and (–)-sesamin (9).<sup>32</sup>

Compound 1 was obtained as a colorless wax. Its molecular formula was determined to be C<sub>16</sub>H<sub>29</sub>NO<sub>6</sub>, based on quasi-molecular ion peaks in the HR-ESI-MS at m/z 332.2073  $[M+H]^+$  (calcd for  $[C_{16}H_{30}NO_6]^+$ : 332.2068) and m/z $354.1925 \text{ [M+Na]}^+$  (calcd for  $[C_{16}H_{29}NO_6Na]^+$ : 354.1887). The <sup>1</sup>H-NMR showed signals of two pairs of olefinic protons [ $\delta_{\rm H}$  6.02 (d, J = 15.6 Hz, H-2)/6.82 (dt, J = 7.2, 15.6 Hz, H-3) and 5.79 (2H, overlapped, H-8 and H-9)], four oxygenated methine protons [ $\delta_{\rm H}$  3.50 (m, H-6), 3.67 (m, H-11), 3.91 (t, J = 4.8 Hz, H-10) and 3.96 (t, J = 4.8 Hz, H-7)], three methylene protons [ $\delta_{\rm H}$  2.41 and 2.27 (m, H<sub>2</sub>-4), 1.53 and 1.71 (m,  $H_2$ -5), 3.24 (s,  $H_2$ -1')], and three methyl groups  $[\delta_{\rm H} 1.15 (3H, d, J = 6.0, H-12), 1.17 (6H, s, H_3-3', H_3-4')].$ The <sup>13</sup>C-NMR and DEPT spectra of compound 1 revealed signals for 16 carbons, including a carbonyl carbon [ $\delta_{\rm C}$  169.1 (C-1)], an oxygenated quaternary carbon [ $\delta_{\rm C}$  71.6 (C-2')], four olefinic methine carbons [ $\delta_{\rm C}$  124.8 (C-2), 132.9 (C-9), 133.0 (C-8), 145.8 (C-3)], four oxygenated methine carbons  $[\delta_{\rm C} 71.6 \text{ (C-11)}, 74.8 \text{ (C-6)}, 76.6 \text{ (C-7)}, 77.3 \text{ (C-10)}], \text{ three}$ methylene carbons [8<sub>C</sub> 29.4 (C-4), 32.3 (C-5), 51.1 (C-1')],

and three methyl carbons [ $\delta_{\rm C}$  18.7 (C-12), 27.2 (C-3' and C-4')]. This evidence suggests that compound 1 is an aliphatic acid amide with a usual skeleton-type from the Zanthoxylum species.<sup>16,20,29</sup> Proton assignments of the main chain were indicated by strong COSY correlations H-2/H-3/H-4/H-5/H-6/H-7/H-8/H-9/H-10/H-11/H-12. The position of first double bond, located at C-2/C-3, was confirmed by HMBC correlations of H-2 ( $\delta_{\rm H}$  6.02) and H-3 ( $\delta_{\rm H}$  6.82) with C-1 ( $\delta_{\rm C}$  169.1), and hence, positions of the remaining double bond (C-8/C-9) and four hydroxyl groups (C-6, C-7, C-10, C-11), located in the main chain, were also determined through back-bone COSY correlations. The HMBC correlation between H-1'  $(\delta_H 3.24)$  and C-1 ( $\delta_C 169.1$ ), as well as the downfield chemical shift of both H-1' ( $\delta_C$  3.24) and C-1' ( $\delta_C$  51.1) suggest an amide connectivity between C-1 and C-1'. The last hydroxyl group was attached at C-2', which was confirmed by HMBC correlations of a magnetically equivalent pair of methyl protons at H-3' and H-4' ( $\delta_{\rm H}$  1.17) with C-2' ( $\delta_{\rm C}$  71.6) and C-1' ( $\delta_{\rm C}$  51.1). Next, configuration of the double bond at C-2/ C-3 was determined to be "E" by J coupling constants of the corresponding olefinic protons ( $J_{\text{H-2/H-3}} = 15.6$  Hz). Due to overlapping signals between H-8 and H-9, configuration of the double bond at C-8/C-9 was determined through its p-bromobenzoyl derivative, 1a. The J coupling constant  $(J_{\text{H-8/H-9}} = 16.0 \text{ Hz})$  in <sup>1</sup>H-NMR of compound **1a** indicated *E*configuration of the double bond at C-8/C-9 in both compounds 1a and 1. Consequently, the chemical structure of compound 1 was determined to be 6,7,10,11-tetrahydroxyl-N-(2-hydroxyl-2-methylpropyl)-2E,8E-dodecadienamide, and termed ZPamide F.

Due to four hydroxyl groups in close proximity (C-6, C-7, C-10, C-11), we attempted to identify the absolute configuration of compound 1 by X-ray crystallography. Using the heavy atom method, compound 1 reacted with p-bromo-

Inflammatory Components from Zanthoxylum Piperitum

benzoyl chloride and was converted into its *p*-bromobenzoate ester, **1a**.<sup>33</sup> Unfortunately, the product of compound **1a** was obtained as an amorphous powder and was thus unable to recrystallize. To date, nearly all aliphatic acid amides compounds from the *Zanthoxylum* species have been isolated as a racemic, and their absolute configurations have not yet to be determined.<sup>16</sup> Thus, a lack of supporting literature and limited experiments prevented the complete determination of the absolute configuration of compound **1**. A total selective synthetic pathway to identify the absolute configuration of aliphatic acid amide compounds from *Zanthoxylum*, as well as ZP-amide F (**1**), will be required for future studies.

Isolated compounds 1-9 were assessed for their effects on TNF $\alpha$ -induced NF- $\kappa$ B transcriptional activity in human hepatocarcinoma (HepG2) cells using an NF- $\kappa$ B-luciferase assay. First, the cytotoxicity of each compound was examined. Cell viability was measured by the MTS colorimetric assay using the Cell Counting Kit-8 reagent. Compounds 1-9 had no significant cytotoxicity in HepG2 cells up to 50.0  $\mu$ M (data not shown), and hence, these compounds were used at alternate concentrations (< 50  $\mu$ M) in subsequent experiments. Among the tested compounds, compounds 7 and 9 significantly inhibited TNF $\alpha$ -induced NF- $\kappa$ B transcriptional activity in a dose-dependent manner (Figure 3) with IC<sub>50</sub> values of 5.50 and 8.10  $\mu$ M, respectively; other compounds

**Figure 3.** Effects of compounds 1–9 on the TNF $\alpha$ -induced NF- $\kappa$ B luciferase reporter activity in HepG2 cells. Data were expressed as mean  $\pm$  SD of at least three experiments performed in triplicate. Statistical significance is determined by one-way analysis of variance followed by Dunnett's multiple comparison test, P < 0.05 versus control.

**Table 2.** PPARs transactivational activities of compounds 1-9. EC<sub>50</sub>: the concentration of a tested compound that gave 50% of the maximal reporter activity

Compounds	EC50 (µM)
1	$> 50^{a}$
2	> 50
3	$47.12 \pm 3.57$
4	$19.13 \pm 3.24$
5	> 50
6	$12.02 \pm 1.20$

8	> 50
9	> 50
Rosiglitazone	$1.60\pm0.07$

<sup>*a*</sup>A compound was considered inactive with  $EC_{50} > 50 \mu M$ . The values were expressed as mean  $\pm SD (n = 3)$ 

were inactive in this assay. Apigenin (IC<sub>50</sub> 1.64  $\mu$ M) was used as a positive control. We continuously investigated the effects of compounds 1-9 on PPAR activity using a nuclear transcription PPRE cell-reporter system. The results showed that compounds 4 and 6 greatly enhanced PPAR transcriptional activity with EC<sub>50</sub> values of 19.13 and 12.02 µM, respectively (Table 2). Compound 3 displayed moderate activity, with an EC<sub>50</sub> value of 47.12 µM, whereas compounds 1, 2, 5, and 7–9 were inactive. Therefore, the PPAR transactivational effects of compounds 3, 4 and 6 were further examined on individual PPAR subtypes, including PPAR $\alpha$ , PPAR $\beta(\delta)$  and PPAR $\gamma$ , using the GAL-4-PPAR chimera assay. As shown in Table 3, compound 4 exhibited increased transactivational activity on PPARa only; at 10 µM, this enhancement was twofold higher compared with the vehicle. However, compound 4 displayed a weak increase on PPARa transactivational activity after dilution to 0.1 µM. Interest-

	1.0	$94.41 \pm 5.93$	$105.39 \pm 9.71$	$100.83\pm8.69$
	10.0	$104.37\pm6.68$	$116.67 \pm 0.00$	$99.47 \pm 5.47$
Ciprofibrate	1.0	$312.59 \pm 64.76$	_	-
L-165041	1.0	_	$291.18\pm28.93$	-
Rosiglitazone	1.0	_	_	$294.99\pm32.85$

**Table 3.** PPAR $\alpha$ , PPAR $\beta(\delta)$ , and PPAR $\gamma$  transactivational activity of compounds **3**, **4**, **6**. Ciprofibrate, L-165041, and rosiglitazone were used as positive controls for PPAR $\alpha$ , PPAR $\beta(\delta)$ , and PPAR $\gamma$ , respectively

ingly, compound **3** moderately activated all PPAR subtypes, whereas compound **6** showed a weak enhancement effect. The PPAR agonist ciprofibrate, L-165041, and rosiglitazone, were used as positive controls for PPARα, PPARβ( $\delta$ ) and PPAR $\gamma$  subtype experiments, respectively (EC<sub>50</sub> 2.84, 1.58 and 3.89 µM). These results led us to conclude that several aliphatic acid amides (**3**, **4** and **6**) and phenolic compounds (**7** and **9**) from the pericarps of *Z. piperitum* exhibit significant anti-inflammatory effects by enhancing PPAR transactivational activity and inhibiting TNFα-induced NF-κB activation. These results also provide scientific support for the use of *Z. piperitum* in the prevention of inflammatory and metabolic diseases.

# Experimental

**General Procedures.** Optical rotations were determined using a Jasco DIP-370 automatic polarimeter. The FT-IR spectra were measured using a Jasco Report-100 infrared spectrometer. The NMR spectra were recorded using a JEOL ECA 600 spectrometer (<sup>1</sup>H, 600 MHz; <sup>13</sup>C, 150 MHz). Highresolution electrospray ionization mass spectra (HR-ESI-MS) were obtained using an Agilent 6530 Accurate-Mass Q-TOF LC/MS system. Column chromatography was performed using a silica gel (Kieselgel 60, 70-230, and 230-400 mesh, Merck, Darmstadt, Germany), YMC RP-18 resins, and thin layer chromatography (TLC) was performed using pre-coated silica-gel 60 F<sub>254</sub> and RP-18 F<sub>254</sub>S plates (both 0.25 mm, Merck, Darmstadt, Germany).

**Plant Material.** The pericarps of *Z. piperitum* were purchased at Daekwang Farm, Busan, Korea in October, 2012 and were taxonomically identified by one of authors (Prof. Young Ho Kim). A voucher specimen (CNU12111) was deposited at the Herbarium of College of Pharmacy, Chungnam National University, Daejeon, Korea.

**Extraction and Isolation.** The pericarps of *Z. piperitum* (3.0 kg) were extracted with MeOH under reflux for 3 h (5 L  $\times$  3 times) to yield 496 g of extract. Crude extract was

suspended in water and then partitioned successively with nhexane, CH<sub>2</sub>Cl<sub>2</sub>, EtOAc, and *n*-BuOH to give *n*-hexane (96.0 g), CH<sub>2</sub>Cl<sub>2</sub> (118.0 g), EtOAc (19.0 g), and *n*-BuOH (174.0 g) fractions, respectively. The EtOAc extract (15.0 g) was subjected to silica gel column chromatography, eluted with gradient solvent system of CH2Cl2/MeOH/H2O (1/0/0, 40/1/0.1, 20/1/0.1,10/1/0.1, 5/1/0.1, 1/1/0.1; v/v/v, 1 L for each step) to give 6 fractions EA1-EA7. Fraction EA2 (4.2 g) appeared precipitate which was filtered and washed with MeOH to afford compound 7 (2.0 g). The filtrate was subjected to YMC column chromatography eluting with MeOH/H<sub>2</sub>O (2.2/1, v/v) to yield five fractions (EA2A-EA2E). Compound 9 (30.0 mg) was obtained from recrystallization fraction EA2E (350.0 mg) in acetone. Fraction EA3 (2.0 g) was subjected to silica gel column, eluted with EtOAc/MeOH (1/1, v/v) to yield six sub-fractions (EA3A-EA3F). Sub-fraction EA3C (110.0 mg) was separated using YMC column with MeOH/H<sub>2</sub>O (1/1, v/v) as eluent to afford compound 8 (10.0 mg). Fraction EA5 (2.2 g) was subjected to silica gel column chromatography, eluted with gradient solvent system of *n*-hexane/acetone  $(3/1 \rightarrow 1/1, v/v)$  to give four fractions (EA5A–EA5D). Fraction EA5C (500.0 mg) was separated by sephadex LH-20 column eluting with MeOH/CH<sub>2</sub>Cl<sub>2</sub> (2/1, v/v) to yield five smaller fractions (EA5C1-EA5C5). Fraction EA5C2 (90.0 mg), and EA5C3 (75.0 mg) were purified through YMC column eluting with MeOH/H<sub>2</sub>O (2/3, v/v) to obtain compounds 2 (11.0 mg) and 4 (15.0 mg), and 3 (13.0 mg), respectively. Fraction EA5C5 (110.0 mg) was separated using YMC column, eluted with MeOH/H<sub>2</sub>O (1/1.6) to yield compounds 5 (13.0 mg) and 6 (15.0 mg). Finally, fraction EA6 (2.8 g) was subjected to silica gel column, eluted with  $CH_2Cl_2/MeOH/H_2O$  (5/1/0.1, v/v/v) to yield seven fractions (EA6A–EA6G). Fraction EA6D (70.0 mg) was further purified on an YMC column eluting with MeOH/H<sub>2</sub>O (1/4, v/v) to obtain compound 1 (16.0 mg).

**ZP-amide F tetra-***p***-bromobenzoate (1a):**  $C_{44}H_{41}Br_{4}NO_{10}$ , white powder, HR-ESI-MS *m/z* (relative intensity) 1085.9287 (100%) [M+Na]<sup>+</sup> (calcd for [ $C_{44}H_{41}Br_4NO_{10}Na$ ]<sup>+</sup>: 1085.9321) <sup>1</sup>H-NMR (CDCl<sub>3</sub>, 400 MHz)  $\delta_{\rm H}$  7.40-7.80 (H-aromatic), 6.73 (dt, *J* = 7.2; 15.6 Hz), 6.01 (dd, *J* = 5.2; 16.0 Hz), 5.95 (dd, *J* = 5.2, 16.0 Hz), 5.69 (dd, *J* = 4.0; 5.2 Hz), 5.67 (d, *J* = 15.6 Hz), 5.62 (dd, *J* = 4.0; 5.2 Hz), 5.42 (m), 5.29 (dt, *J* = 4.0; 8.8 Hz), 4.31 (s), 2.02 (q, *J* = 7.6 Hz), 1.63 (s), 1.62 (overlapped), 1.35 (d, *J* = 7.2 Hz).

Cell Culture and Reagents. Human hepatocarcinoma HepG2 cells were maintained in Dulbecco's modified Eagles' medium (DMEM) (Invitrogen, Carlsbad, CA) containing 10% heat-inactivated fetal bovine serum (FBS), 100 units/ mL penicillin, and 10  $\mu$ g/mL streptomycin at 37 °C and 5% CO<sub>2</sub>. Human TNF- $\alpha$  was purchased from ATgen (Seoul, Korea).

NF-KB-Luciferase Assay. Human hepatocarcinoma HepG2 cells were maintained in Dulbecco's modified Eagles' medium (DMEM) (Invitrogen, Carlsbad, CA) containing 10% heatinactivated fetal bovine serum (FBS), 100 units/mL penicillin, and 10 µg/mL streptomycin at 37 °C and 5% CO<sub>2</sub>. The luciferase vector was first transfected into cells. After a limited amount of time, the cells were lysed, and luciferin, the substrate of luciferase, was introduced into the cellular extract along with Mg<sup>2+</sup> and an excess of ATP. Under these conditions, luciferase enzymes expressed by the reporter vector could catalyze the oxidative carboxylation of luciferin. Cells were seeded at  $2 \times 10^5$  cells per well in a 12-well plate and grown. After 24 h, cells were transfected with inducible NF-kB luciferase reporter and constitutively expressing Renilla reporter. After 24 h of transfection, medium was changed to assay medium (Opti-MEM + 0.5% FBS + 0.1 mM NEAA + 1 mM sodium pyruvate + 100 units/mL penicillin + 10 µg/mL streptomycin) and cells were pretreated for 1 h with either vehicle (DMSO) and compounds, followed by 1 h of treatment with 10 ng/mL TNF- $\alpha$  for 20 h. Unstimulated cells were used as a negative control (-), apigenin was used as a positive control. Dual Luciferase assay was performed 48 h after transfection, and promoter activity values are expressed as arbitrary units using a Renilla reporter for internal normalization.

**PPRE-Luciferase Assay.** Human hepatoma cells (HepG2) were seeded at  $1.5 \times 10^5$  cells per well in 12-well plates and grown for 24 h before transfection. An optimized amount of DNA plasmid (0.5 µg of PPRE-Luc and 0.2 µg of PPAR-inpCMV) was diluted in 100 µL of DMEM. All cells were transfected with the plasmid mixture using WelFect M Gold (WelGENE Inc.) as described by the manufacturer. After 30 min of incubation at room temperature, the DNA plasmid solution (100 µL) was introduced and mixed gently with cells. After 24 h of transfection, the medium was changed to TOM (Transfection Optimized Medium, Invitrogen) con-

taining 0.1 mM NEAA, 0.5% charcoal-stripped FBS, and the individual compounds (test group), dimethyl sulfoxide (vehicle group), or rosiglitazone (positive control group). The cells were then cultured for 20 h. Next, the cells were washed with PBS and harvested with 1× passive lysis buffer (200  $\mu$ L). The intensity of emitted luminescence was determined using an LB 953 Autolumat (EG&G Berthold, Bad Wildbad, Germany).<sup>35,36</sup>

PPAR Subtype Specific Transactivational Assay. Human hepatoma cells (HepG2) were seeded at  $1.5 \times 10^5$  cells per well in 12-well plates and grown for 24 h before transfection. Cells were transfected separately with one pGal4-PPAR subfamily vector [pFAGal4-PPARα-LBD, pFA-Gal4-PPAR $\gamma$ -LBD, or pFA-Gal4-PPAR $\beta(\delta)$ -LBD expression plasmids], together with pFR-Luc using the WelFect M Gold transfection reagent (WelGENE Inc.), as described by the manufacturer. After 24 h of transfection, the medium was changed to TOM (Invitrogen) containing 0.1 mM NEAA, 0.5% charcoal-stripped FBS, and each compound (test group), dimethyl sulfoxide (vehicle group), ciprofibrate (positive control group for PPAR $\alpha$ ), rosiglitazone (positive control group for PPARy), or L-165041 (positive control group for PPAR $\beta(\delta)$ ). The cells were then cultured for 20 h, after which the cells were washed with PBS and harvested with  $1 \times$  passive lysis buffer (200 µL). The intensity of emitted luminescence was determined using a Centro LB 960 microplate luminometer (EG&G Berthold) by measuring light emission for 5 s.<sup>37</sup>

**Statistical Analysis.** All data represent the mean  $\pm$  standard deviation (SD) of at least three independent experiments performed in triplicate. Statistical significance is determined by one-way analysis of variance followed by Dunnett's multiple comparison test, P < 0.05.

**Supporting Information.** HR-ESI-MS, <sup>1</sup>H-, <sup>13</sup>C-NMR, HMQC, HMBC and COSY spectra of compound **1**, <sup>1</sup>H-NMR data of compound **1a** are available as Supporting information.
