Abstract - This study was carried out to get the information of Plum tree (192 germplasm) collected in Korea, and to evaluate the organic acid contents and fermentation solution. The organic acid content of fruit was 50.9 ± 6.0 mg/g, and which was composed of 55.5% of citric acid, 43.4% of malic acid and 1.1% of oxalic acid, and showed large difference among germplasms. Oxalic acid and malic acid made no differences in organic acid content according to flesh color, whereas citric acid and total organic acid contents were highest in orange color and lowest in whitish green. Malic acid, citric acid and total organic acid contents did not show differences among fruit weight groups, but oxalic acid content was highest at fruit weight of 5.1 ~ 10.0 g and lowest at more than 20.1 g. The sugar content of fermentation solution of fruit was 55.7 ± 1.6 °Brix and the harvest rate was $116.7 \pm 8.7\%$. The correlation coefficients among fruit weight, the sugar content (°Brix) and harvest rate of fermentation solution were very low, and there were correlations of $r = -0.551^{**}$ between fruit weight and oxalic acid, $r = -0.767^{**}$ between malic acid and citric acid, and $r = 0.834^{**}$ between citric acid and total organic acid content.

Key words – Fermentation solution, Germplasm, Organic acid, Plum tree, *Prunus mume*

Introduction

Plum tree (*P. mume*) is a deciduous subtree belongs to the *Prunus*, Rosaceae of China origin, which grows currently wild or cultivated in the warm regions of northeast Asia (Song, 1998). Plum tree in Korean peninsula was planted for processing in the Koryo period following the ornamental of the Three Kingdoms period, and now trees with older age and historical properties are being cultivated rarely.

Plum tree fruit (plum) has a number of bioactive substances, exhibiting antibacterial activity, appetite improvement, sterilization, insecticidal action with the prevention of various adult diseases (Yun, 2011).

In addition, plums are mainly used for processing plum wine, drink, concentrate, vinegar, pickle, tea (Lim and Eun, 2012; Yaegaki *et al.*, 2006), so researches on food properties and efficacy have been variously conducted. The main studies of plum are useful components (Cha *et al.*, 1999b;

Kim *et al.*, 2006), and pharmacological effects (Kim *et al.*, 2002; Seo *et al.*, 2008), organic acids (Cha *et al.*, 1999a; Paik *et al.*, 2010) and plum fermentation solution (Seon *et al.*, 2017; Yun, 2011).

Although most of these studies were conducted on improved varieties, resource characteristics of the historical old plum were extremely rare. In particular, the usefulness study for the plum resources in the distribution of all regions in Korea is expected to provide lots of information about the availability of plum.

This study was analyzed on the characteristics of organic acids and plum fermentation solution for the plum fruit of 192 germplasms in order to provide useful information of the plum trees use collected in all regions of South Korea.

Materials and Methods

Experimental materials

The study was conducted on 192 germplasms of *P. mume* (plum trees) planted on Kongju university farm (Fig. 1). Plum

trees are collected and grafted in South Korea and then grown for more than 10 years. Identification of the plum tree was utilized in the literature of Lee (2003). Experimental materials are plum tree fruits (plums) harvested from 2018 to 2019. Organic acid contents of plums were analyzed by selecting 43 germplasm according to the distribution ratio of fruit flesh

color and weight.

Organic acid analysis

The plum samples were collected in June 2018 and stored at -70°C up to 3 months prior to experimental use. After thawing, plum seeds were removed and remaining fleshs were cut into small pieces. One gram of sample was placed in a 50 mL centrifuge tube, and 30 mL of 20 mM potassium phosphate were added and homogenized with a polytron (PT 2500 E, Kinematica AG, Switzerland) at a speed of 1,000 rpm. After centrifugation (Combi-514 R, Hanil, Republic of Korea) at $3,000 \times g$ for 10 min, supernatants were filtered through a syringe filter (nylon, $0.45 \mu\text{m}$, ADVANTEC, Japan) and injected into an HPLC system (S2100, Sykam, Germany). Table 1 shows HPLC instrumental conditions for organic acid analysis and resultant chromatograms for a plum sample and authentic standards of oxalic (OA), malic (MA), and citric (CA) acids are provided in Fig. 2A. Under our experimental conditions OA, MA, and CA showed retention times of 2.92 min, 3.87 min, and 5.75 min, respectively (Fig. 2A). Authentic standards for OA, MA, and CA were

Table 1. Operation conditions of HPLC for organic acid analysis

Item	Condition
Column	Zorbax SB-Aq (4.6 mm \times 250 mm)
Mobile phase	20 mM potassium phosphate
Flow rate	1.0 mL \cdot min $^{-1}$
UV detector	220 nm

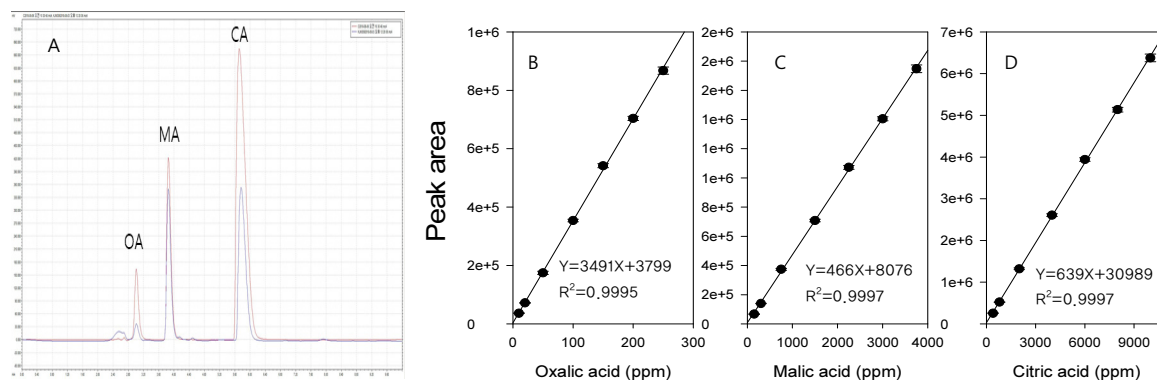

Fig. 2. Chromatograms for sample (blue) and authentic standards (red) (A) and their calibration curves for oxalic (B), malic (C), and citric (D) acids. The retention times for OA, MA, and CA were 2.92 min, 3.87 min, and 5.75 min, respectively. Data in calibration curves represent mean values \pm standard deviation of 6 independent replications.

purchased from Sigma-Aldrich (USA) and standard mixture solutions ranging 10 to 250 ppm, 150 to 3,750 ppm, and 400 to 10,000 ppm, respectively, were prepared to evaluate plum germplasm samples with diverse range of organic acid contents. Validations for organic acid analysis methods were performed prior to sample analyses. The recovery rates for OA, MA, and CA tested at 3 different levels with 6 replications for each level were 91.3%-98.9%, 90.8%-97.6%, and 84.0-89.1%, respectively. Limit of detection (LOD) and limit of quantitation (LOQ) were 2.88 and 8.74 ppm for OA, 36.8 and 111.5 ppm for MA, while CA showed 81.4 and 246.7 ppm, respectively. Relative standard deviations (RSD, in %) for repeatability tests based upon 6 replicated injections of 7 levels of authentic standards and reproducibility tests based upon 6 inter-date injections of 7 levels of standards were 1.1-3.2% and 1.5-4.8% for OA, 1.0-2.9% and 2.0-4.7% for MA, and 1.0-3.4% and 1.9-4.3% for CA, respectively.

Fermentation solution analysis

The plums of experimental materials were used through the process of washing and drying after harvesting in June 2019. The plums of 200 to 300 g were stored at normal temperature by sealing up in a plastic airtight container with the same amount of white sugar. Sugar content of fermentation solution was measured three times by opening a closed container in October 2019 with a fruit sugar index meter (Giwon high-tech GMK-706R). Sugar content was analyzed by selecting a

uniform 148 germplasms of fermentation solution, the total harvest rate of 192 germplasms is shown in fermentation solution (mL)/weight (g) of plum.

Statistical analysis

Statistics analyzed the correlation and average difference between characteristics using the SPSS 23.

Results and Discussion

Organic acids content

The content of organic acids by fruit flesh color is the same as Table 2. The total organic acid content was 50.9 ± 6.0 mg/g. In the contents by fruit flesh colors, orange color was the highest as the 54.3 ± 8.5 mg/g, the next, light orange (52.3 ± 4.2 mg/g) and whitish green (48.1 ± 4.7 mg/g) was followed. In the contents by organic acids, citric acid was the highest as the 28.3 ± 9.0 mg/g, 55.5%, the next, malic acid (22.1 ± 5.2 mg/g, 43.4%) and oxalic acid (0.55 ± 0.32 mg/g, 1.1%) was followed. It was similar to the report of So (2013) that the citric acid was contained the highest as $2.0 \sim 3.3$ mg/mL in the plums.

Content of oxalic acid and malic acid was a few in difference by fruit flesh color, but the citric acid content showed a difference, which the orange color was the highest and whitish green was the lowest. The organic acids content in fruit flesh color was different; whitish green did show little difference in the content of malic acid and citric acid, but

Division	Sugar content (°Brix)						Range	Mean ± S.D	C.V (%)
	50.0 below	50.1 ~ 52.0	52.1 ~ 54.0	54.1 ~ 56.0	56.1 ~ 58.0	58.1 over			
rate (%)	1.6	6.5	12.5	37.0	29.2	2.6	48.8 ~ 59.7	55.7 ± 1.6	2.9

citric acid is higher 20.0%, 18.6%, respectively than the malic acid in the light orange and orange.

The content of organic acids by plum weight is the same as Table 3. The content of malic acid, citric acid with total organic acid did not show a difference by weight, and oxalic acid showed a difference by weight. In oxalic acid, the weight 5.1 ~ 10.0 g (0.77 ± 0.27 mg/g) was the highest, and the more than 20.1 g (0.21 ± 0.24 mg/g) was the lowest.

In more than 20.1 g weight, the difference between citric acid and malic acid is very little, but other weight groups were 5.7 to 27.4% higher than citric acid.

In citric acid content, the lower plum weight grew, the higher tendency was. The citric acid content contained the most commonly in the plum showed a certain tendency in other studies; malic acid and oxalic acid content is reduced by plum maturation and showed annual variations, but citric acid was increased by plum maturation and no showed annual variations (Gwak *et al.*, 2018; Kim, 2017).

Sugar content and harvest rate of fermentation solution

The sugar content of the fermentation solution was an average of 55.7 ± 1.6 °Brix, range 48.8 to 59.7 °Brix (Table 4). Sugar content distribution was the highest in 54.1 to 56.0 °Brix (37.0%), followed by 56.1 to 58.0 °Brix (29.2%), 52.1 to 54.0 °Brix (12.5%).

The sugar content of the fermentation solution showed a variety of individuals, in spite of the same ratio and the same fermentation period of the plum and sugar, but did not show a significant difference in the individuals because variation coefficient is lowered to 2.9. Therefore, the sugar content of the fermentation solution is believed to affect more difference of the sugar ratio and fermentation period than the same conditions. So (2013) reported that the longer the fermentation period became, the less sugar of the plum fermentation solution grew.

The harvest rate of the fermentation broth was wide as an average of $116.7 \pm 8.7\%$, range 91.3 to 134.1%, as table 5, the

Table 5. Distribution of the harvest rate of fermentation solution of *P. mume* germplasms

Division	Harvest rate (%) ^z						Range	Mean \pm S.D	C.V (%)
	105.0 below	105.1 ~ 110.0	110.1 ~ 115.0	115.1 ~ 120.0	120.1 ~ 125.0	125.1 over			
rate (%)	9.3	9.9	23.4	20.3	20.8	16.2	91.3 ~ 134.1	116.7 \pm 8.7	7.4

^z[fermentation solution (mL) / fruit weight (g)] \times 100.

Table 6. Correlation coefficients for soluble solid content ($^{\circ}$ Brix), fruit weight, the sugar content ($^{\circ}$ Brix) and harvest rate of fermentation solution of *P. mume* germplasms

Division	Fruit weight	Sugar content ($^{\circ}$ Brix)	Harvest rate
Soluble solid content ($^{\circ}$ Brix)	0.055	0.125	-0.052
Fruit weight	-	-0.086	0.150*
Sugar content ($^{\circ}$ Brix)	-	-	0.180*

*Significance at $p < 0.05$.

Table 7. Correlation coefficients for fruit weight and organic acid contents of *P. mume* germplasms

Division	Oxalic acid	Malic acid	Citric acid	Total organic acid
Fruit weight	-0.551**	0.270	-0.203	-0.103
Oxalic acid	-	0.039	-0.142	-0.126
Malic acid	-	-	-0.767**	-0.288
Citric acid	-	-	-	0.834**

**Significance at $p < 0.01$.

coefficient of variation was higher than the sugar content indicating 7.4. The distribution of yield sped up from 110.1 to 115.0% to 23.4%, followed by 120.1 to 125.0% (20.8%), 115.1 to 120.0% (20.3%) it was followed by:

Correlation

Correlation coefficients between sugar content and weight of the plum, correlation coefficients between the sugar content of fermentation solution and harvest rate were very low. The relationship harvest rate between the fermentation solution sugar content and weight of the plum was the correlation coefficient of $r=0.180^*$, $r=0.150^*$, respectively, they marked the relevance between the two characteristics because showed significance by 5% (Table 6).

The relationship between the plum weight and the organic acid content had a tendency of lowering the content of oxalic acid when the plum weight was heavier, because the oxalic acid and plum weight was recognized as $r=-0.551^{**}$ correl-

ation. Correlation by organic acid showed a correlation of $r=-0.767^{**}$ between the malic acid and citric acid, and $r=0.834^{**}$ between citric acid and the total organic acid (Table 7).

In the above results, the main organic acid of the plum was citric acid, malic acid, oxalic acid as reported by Kim (2017). The total organic acid content of the plums was lots of changes in high and low contents by the individual and organic acids, and the ratio of the content was also different by the individual. The diversity of this organic acid content is inferred to be related to the taste and aroma and harvest rate of the plum fermentation solution, there it needs the relevance of these elements by various analytical methods in the future.

In the fermentation solution of the plum, because of variety of individuals in sugar content and harvest rate, the possibility of developing a variety of products utilizing these resources will be greatly increased, if the additional researches are performed on this project.
