ABSTRACT

Botrylloides violaceus is native to the Northwest Pacific, including Korea. This species has many color variations in alive condition and a variety of zooid compound forms, and therefore difficult to identification in the field survey. This is the first report of COI DNA barcodes of B. violaceus from Korea. The intra-specific pairwise distance between Korean and UK populations had ranged from 1.4% to 2.6%. The inter-specific variations between B. violaceus and other Botrylloides species were 21.0–36.8%. The new DNA barcodes for Korean B. violaceus may be helpful in the identification of colonial ascidians, which is a difficult task when based on morphological identification.

Keywords: DNA barcoding, COI, colonial ascidian, Styelidae, Botrylloides

INTRODUCTION

The genus Botrylloides Milne Edwards, 1841 is one of popular colonial ascidians in the world and currently comprises 19 species (Shenkar et al., 2020). Among them, two species have been reported in South Korea: B. magnicoecum (Hartmeyer, 1912) and B. violaceus Oka, 1927 (Rho, 1977; Rho et al., 2000). Botrylloides violaceus is native to the Northwest Pacific, including Korea (Cohen, 2011), but has also been reported as a non-indigenous species (NIS) from western North America and Europe (Gittenberger and Moons, 2011; Simkanin et al., 2013; Viard et al., 2019). The lack of ascidian-specialized taxonomists and the consequent frequent misidentification of samples have been among the major limiting factors in the ability to detect NIS of ascidians (Izquierdo-Muñoz et al., 2009). The identification of ascidians (especially colonial ascidians) based on morphological taxonomy is a difficult task owing to many limitations, particularly of the colonial form, and this has led to misidentification of the species (Lambert, 2009; Geller et al., 2010). The efficiency of DNA barcoding was confirmed for the identification of several ascidians and resolved the limitations of identification through conventional taxonomy (Akram et al., 2017). In this study, we obtained partial sequences of cytochrome c oxidase subunit I (COI) from B.

violaceus in South Korea, where is a part of the type locality for this species, and compared them with *COI* sequences of *B. violaceus* from UK and other *Botrylloides* species retrieved from GenBank.

The colonies were collected from artificial material (resin acrylic plate) in six harbors of South Korea and labelled each of the collected colonies: Dangjin, Gunsan, Incheon, Jukbyeon, Ulsan, and Yeosu (Fig. 1). All examined colonies were deposited in 95% ethyl alcohol solution at the Marine Biological Resource Institute of Sahmyook University. We the observed morphological characteristics using a microscope and identified as B. violaceus based on Rho (1977) and Tokioka (1967). Total genomic DNA was extracted from a single zooid in a colony by following the DNeasy Blood and Tissue kit protocol (Qiagen, Hilden, Germany). The partial sequences of COI were amplified using primer pairs as follows: LCO1490-HCO2198 (Folmer et al., 1994) and dinF-Nux1R (Brunetti et al., 2017). The polymerase chain reaction was performed on a 20.0 µL total reaction volume (AccuPower PCR PreMix & Master Mix; Bioneer, Seoul, Korea) including 1.0 µL of each primer (10 mM) and 0.5 μ L of DNA template (>50 ng/ μ L), using the following thermal cycling profile: one cycle at 94°C for 3 min; 35 cycles of 94°C for 30 s, 50°C for 45 s, and 72°C for 60 s; and a 7 min final extension at 72°C. The pairwise

distance (p-distance) was calculated using the Kimura 2-parameter model (K2P) (Kimura, 1980) and neighbor-joining (NJ) tree was constructed with 1,000 bootstrapping replicates using the K2P in MEGA 7.0 (Kumar et al., 2016).

RESULTS AND DISCUSSION

Botrylloides violaceus had many variations in zooid compound form and color in alive condition, and therefore difficult to identification immediately in the field survey. In this study, we labeled each colony by color and all labeled colonies were identified as *B. violaceus* based on morphological characteristics (Table 1). We obtained newly 10 partial *COI* sequences of Korean *B. violaceus*, which were 672 bp or 858 bp (Table 1). The variations within Korean and UK populations were 0.0–2.6% and 0.2–0.9%, respectively (Table 2). And, the intra-

specific variations between Korean and UK populations were 1.4–2.6%, which were slightly higher than those of other *Botrylloides* species, 0.2–0.9% for *B. diegensis*, 0.2–0.5% for *B. leachii* and 1.4% for *B. nigrum* (Table 2). The inter-specific variations between *B. violaceus* and other seven *Botrylloides* species were 21.0–36.8% (Table 2). Based on the NJ tree, although they showed various colors and zooid compound forms, all *COI* barcodes of *B. violaceus* formed a single clade separated from other *Botrylloides* species (Fig. 2). This study contributes in identifying *B. violaceus* and understanding taxonomic relationship of *Botrylloides* species.
